Objectives

- Improve the expressively of normalizing flow to model data distributions on (finite sets of) differentiable manifolds. Handle arbitrary topology of the data space, and different dimensionality than the latent space.
- Provide a statistical framework for combining normalizing flows from different charts.
- Empirical validation of improved density estimation and sample generation, scaling to high dimensional image data (MNIST).

Introduction

Unlike other generative models, normalizing flows (NFs) have the advantage of allowing for exact density estimation [1]. Unfortunately, this benefit comes at the cost of requiring the flow to be a diffeomorphism (a.e.), restricting the applicability of NFs to data manifolds that are diffeomorphic to the latent space $\mathcal{Z}$. In particular, the data must have the same dimension as $\mathcal{Z}$ if the NF is to perform well. We overcome these limitations by viewing NFs as chart maps of the data manifold, thus allowing for data manifolds with more complex topology. Our main contributions are:

- A scalable method of learning good charts using a vector quantized auto-encoder.
- A statistical and scalable (to high dimensions) framework for combining normalizing flows from different charts.

The chart regions $U_1, \ldots, U_K$

A VQ-AE learns an encoder map $E: \mathcal{X} \rightarrow \mathcal{V}$, a decoder map $D: \mathcal{V} \rightarrow \mathcal{X}$, and a collection of "chart centers" $Q = \{v_k \in \mathcal{V} \mid k \in \mathcal{K}\}$ that minimize the error $\mathcal{L}(D(g_{\text{mean}}(x) - E(x)), x)$. Once $D$ is trained, we learn a coarse quantization map $d_k(x) = ||E(x) - v_k||_2$ for $k = 1, \ldots, K$. We would like charts to overlap, but also to be sparse in the sense that no $x$ has too many charts. Fix $\epsilon > 0$, let $d_1 \leq \cdots \leq d_K$ be the sorted permutation of $d_1, \ldots, d_K$ then define $U_k = \{x \mid ||E(x) - v_k||_2 < (1 + \epsilon) d_k\}$.

The chart maps $f_1, \ldots, f_K$

We model $g_k : \mathcal{Z} \rightarrow U_k$ as L layered invertible NFs. To handle dimensionality change, we post-compose with a conformal dimension raising map [2] so that $g_k = c_1 g_k^1 \circ \cdots \circ g_k^L = f_k^L \circ \cdots \circ f_k^1$. In practice, we reduce the number of parameters of our model by restricting each $g_k^l$ (and $f_k^l$) to depend on $k$ only through the value of the encoded chart center $v_k$. $g_k, g_k, \ldots, g_k$ are learned via gradient descent on the objective function (2).

- Sampling: $z$ and $k$ are independent, so sample $z \sim g_k(z)$ and $k \sim p(k)$ and then compute $x = g_k(z)$.
- Inference: One can perform a stochastic inference via sampling $k \sim p(k|x)$ and computing $z = f_k(x)$, however if deterministic inference is preferred one may instead use $z = \mathbb{E}_{k \sim p(k|x)}[f_k(x)] = \sum_{k \in \mathcal{K}} p(k|x) f_k(x)$.

Results

- Figure: Qualitative visualization of the samples generated by a classical flow. RealNVP (Middle Row) and its VQ-counterpart (Bottom Row) trained on Toy 3D data distributions (Top Row).
- Figure: FID scores (lower the better) across the training of (a) RealNVP and (b) MAF on the MNIST dataset. The shaded region represents the standard deviation over 3 trials.

Future Work

Our framework is well suited to high-dimensional datasets (such as natural images) that obey the manifold hypothesis, an avenue we hope to explore in the sequel.

Exact Density Evaluation

Denote by $\mathcal{Z}$ the latent space, $\mathcal{X}$ the data space, and $\mathcal{M} \subset \mathcal{X}$ the data manifold. Let $(U_k)_{k \in \mathcal{K}}$ be such that $\mathcal{M} \subset U_1 \supset U_2 \supset \cdots \supset U_K$ and let $\mathcal{V}_k := U_k \cap \mathcal{M}$. Assume there exist $D_k : \mathcal{V}_k \rightarrow \mathcal{Z}$ so that $\mathcal{V}_k = g_k(D_k)$ for some immersion $g_k : D_k \rightarrow U_k$ with inverse $f_k : V_k \rightarrow D_k$. If $x$ is a r.v. supported on $\mathcal{M}$, $z$ is a r.v. in $\mathcal{Z}$, $k$ is a discrete random variable and $x, z, k$ have joint distribution

$$p(x, z, k) = \delta(x - g_k(z))q(z)p_k$$

Then

$$p(x) = \sum_{k \in \mathcal{K}} p_k \left\{ \det (J f_k(x) J f_k(x)^T) \right\}^2 q(f_k(x))$$ (2)
