Abstract

In this paper we give an extension of Barbashin-Krasovski-LaSalle Theorem to a class of time-varying dynamical systems, namely the class of systems for which the restricted vector field to the zero-set of the time derivative of the Liapunov function is time invariant and this set includes some trajectories. Our goal is to improve the sufficient conditions for the case of uniform asymptotic stability of the equilibrium. We obtain an extension of a well-known linear result to the case of zero-state detectability (given \((C, A)\) a detectable pair, if there exists a positive semidefinite matrix \(P \geq 0\) such that: \(A^T P + PA + C^T C = 0\) then \(A\) is Hurwitz - i.e. it has all eigenvalues with negative real part) as well as a result about robust stabilizability of nonlinear affine control systems.

Key words: Invariance Principle, Liapunov functions, detectability, robust stabilizability

1 Introduction and Main Result

Let us consider the following time-varying dynamical system:

\[
\dot{x} = f(t, x), \quad x \in D, t \in \mathbb{R}
\]  

(1)

where \(D\) is a domain in \(\mathbb{R}^n\) containing the origin \((0 \in D \subset \mathbb{R}^n)\). About \(f\) we suppose the following:

1) \(f(t, 0) = 0\), for any \(t \in \mathbb{R}\);
2) Uniformly continuous in \(t\), for any \(x \in D\) fixed;
3) Uniformly local Lipschitz continuous in \(x\) for any \(t \in \mathbb{R}\), i.e. for any compact set \(K \subset D\), there exists a positive constant \(L_K > 0\) such that:

\[
\| f(t, x) - f(t, y) \| \leq L_K \| x - y \|, \quad \text{for any } x, y \in K \text{ and } t \in \mathbb{R}
\]

4) bounded in time, that means there exists a continuous function \(M : D \rightarrow \mathbb{R}\) such that:

\[
\| f(t, x) \| \leq M(x), \quad \text{for any } t \in \mathbb{R}
\]

With these hypothesis we know that for any \((t_0, x_0) \in \mathbb{R} \times D\) there exists an unique solution of the Cauchy problem:

\[
\begin{align*}
\dot{x} &= f(t, x) \\
x(t_0) &= x_0
\end{align*}
\]  

(2)
with the initial data \((t_0, x_0)\); we denote by \(x(t; t_0, x_0)\) this solution.

It is known that this solution can be defined in \(t\) on the interval \((t_0 - T, t_0 + T)\) where \(T = \sup_{x_0 \in \mathbb{D}(x_0) \subset D} \|x(t_0, x_0)\|\), the supremum is taken over all positive radius such that the ball centered around \(x_0\), \(\mathbb{B}_r(x_0) = \{x \in \mathbb{R}^n | \|x - x_0\| < r\}\), is completely included in \(D\) and \(\|f\|_{\mathbb{B}_r(x_0)} = \sup_{(t, x) \in \mathbb{R} \times \mathbb{B}_r(x_0)} \|f(t, x)\|\) is a supremum norm of \(f\) with respect to \(\mathbb{B}_r(x_0)\) (where is no confusion we denote \(\mathbb{B}_r = \mathbb{B}_r(0)\)). It is also known that the function \(\gamma_{t, t_0}(x_0) = x(t; t_0, x_0)\) is well defined for some bounded open set \(S, \gamma_{t, t_0} : S \rightarrow U \subset D (U \text{ open bounded})\) and it is Lipschitz continuous with a Lipschitz constant given by \(L = \exp(L_U |t - t_0|)\) \((L_U\) being the Lipschitz constant associated to \(f\), as above, on the compact set \(U\). All these results may be found in a textbook of differential equations (for instance see [5]).

Our concern regards the stability character of the equilibrium point \(\hat{x} = 0\). Firstly, we recall some definitions about stability (in Lyapunov sense).

**Definition** We say that the equilibrium point \(\hat{x} = 0\) for (1) is **uniformly stable** if for any \(\epsilon > 0\) there exists \(\delta > 0\) such that for any \(t_0 \in \mathbb{R}\) and \(x_0 \in \mathbb{R}\) with \(\|x_0\| < \delta\) the solution \(x(t; t_0, x_0)\) is defined for all \(t \geq t_0\) and furthermore \(\|x(t; t_0, x_0)\| < \epsilon\) for any \(t > t_0\).

**Definition** We say that the equilibrium point \(\hat{x} = 0\) for (1) is **uniform asymptotic stable** if it is uniformly stable and there exists a \(\delta > 0\) such that for any \(t_0 \in \mathbb{R}\) and \(x_0 \in \mathbb{R}\) with \(\|x_0\| < \delta\) the solution \(x(t; t_0, x_0)\) is defined for all \(t \geq t_0\) and \(\lim_{t \rightarrow \infty} x(t; t_0, x_0) = 0\).

If in the definition of uniform stability we swap 'there exists \(\delta > 0\) with 'for any \(t_0 \in \mathbb{R}\)' (thus \(\delta\) will depend on \(\epsilon\) and \(t_0\), \(\delta_{t_0, \epsilon}\)) then we say the equilibrium is (just) **stable**. If we proceed the same in the second definition we obtain that the equilibrium is asymptotic stable. For time-invariant systems there is no distinction between uniform stability and stability, or uniform asymptotic stability and asymptotic stability. In general case, the uniform (asymptotic) stability implies (asymptotic) stability, but the converse is not true (see for instance [6]).

We say that the dynamics (1) has a **positive invariant set** \(N\) if for any \(t_0 \in \mathbb{R}\) and \(x_0 \in N\) the solution \(x(t; t_0, x_0)\) is defined for all \(t \geq t_0\) for which it is well-defined. Then it makes sense to consider the dynamics restricted to \(N\), i.e. the function:

\[
X : \mathbb{R}^+ \times \mathbb{R} \times N \rightarrow N, \quad X(t; t_0, x_0) = x(t + t_0; t_0, x_0)
\]

where \(t\) runs up to a maximal value depending on \((t_0, x_0)\). Moreover, considering the case of \(f\) from (1) we obtain that \(X(t; t_0, 0) = 0\), for any \(t > 0, t_0 \in \mathbb{R}\). Therefore we may define the corresponding properties for the restricted dynamics as above, where we replace \(D\) by \(N\).

The main result of this paper is given by the following theorem:

**Theorem 1** Consider the time-varying dynamical system (1) for which \(f\) has the properties 1) - 4).
Suppose there exists a function \(V : D \rightarrow \mathbb{R}\) of class \(C^1\) such that:

\begin{enumerate}
  \item \(H1\) \(V(x) \geq 0\) for any \(x \in D\) and \(V(0) = 0\);
  \item \(H2\) There exists a continuous function \(W : D \rightarrow \mathbb{R}\) such that:
    \[
    \frac{dV}{dt}(t, x) = \nabla V(x) \cdot f(t, x) \leq W(x) \leq 0
    \]
  \item \(H3\) Let \(E = \{x \in D | W(x) = 0\}\) denote the zero-set (or kernel) of \(W\); suppose that \(f\) restricted to \(E\) is time-invariant (i.e. \(f(t, x) = f(t_0, x)\), for any \(t \in \mathbb{R}\) and \(x \in E\)). Then there exists the maximal positive invariant set, denoted \(N\), included in \(E\), i.e. for any \(x_0 \in N\) and \(t_0 \in \mathbb{R}\), \(x(t; t_0, x_0) \in N\), for any \(t \in [t_0, t_0 + T_0)\) in the maximal interval of definition of the solution.
  
  Then the dynamics (1) has at \(\hat{x} = 0\) an uniformly asymptotic stable equilibrium point if and only if the dynamics restricted to \(N\) has an asymptotic stable equilibrium at \(\hat{x} = 0\).
\end{enumerate}

Even if it has appeared in the literature in a more general setting (I refer to [17]), it is worth mentioning the form that the Invariance Principle is taken in this context:
THEOREM 2 (Invariance Principle) Consider the time-varying dynamical system (1) for which f has the properties 1–4. Suppose there exists a function $V : D \rightarrow \mathbb{R}$ of class $C^1$ such that:

H1) It is bounded below, i.e. $V(x) \geq V_0$ for any $x \in D$ for some $V_0 \in \mathbb{R}$;

H2) There exists a continuous function $W : D \rightarrow \mathbb{R}$ such that:

$$\frac{dV}{dt}(t, x) = \nabla V(x) \cdot f(t, x) \leq W(x) \leq 0$$

H3) Let $E = \{x \in D | W(x) = 0\}$ denote the zero-set (or kernel) of $W$; suppose that $f$ restricted to $E$ is time-invariant (i.e. $f(t, x) = f(t_0, x)$, for any $t \in \mathbb{R}$ and $x \in E$). Then there exists the maximal positive invariant set, denoted $N$, included in $E$, i.e. for any $z_0 \in N$ and $t_0 \in \mathbb{R}$, $x(t; t_0, z_0) \in N$, for any $t \in [t_0, t_0 + T_0]$ in the maximal interval of definition of the solution.

Then any bounded trajectory of (1) tends to $N$, i.e. $(t_0, z_0)$ is the initial data for a bounded solution included in $D$ then:

$$\lim_{t \to \infty} d(x(t; t_0, z_0), N) = 0$$

Remarks 1) There are two directions in which Theorem 1 generalizes the well-known Barbashin-Krasovskii-LaSalle's Theorem (see [11], [12] or [10]); firstly we require $V$ to be only nonnegative and not strictly positive, secondly we consider the time-varying dynamical systems. There exists in literature two earlier results in the first direction that I wish to comment. The first result that I am referring to is Lemma 5 from [4]. In this lemma is considered only an autonomous system and for the restricted dynamics is required to be attractive in the sense that all trajectories should tend to the origin. I point out that only the requirement of attractivity is not enough; this can be seen in a trivial case, namely the 2 dimensional system given by Vinograd (conform [6]), for which the origin is an attractive equilibrium but not stable, and take $V \equiv 0$. I stress out that for the purposes of their paper ([4]) Lemma 5 can be replaced by Theorem 7 of this paper without affecting the other results of that paper.

A second result has appeared in [16] but not in a general and explicit form as here. In fact in [16] the author is concerned with the stability of the large-scale systems which are already decomposed in triangular form. Thus, this result solves the problem only in the case when we can perform the observability decomposition of the dynamics (1) with respect to the output $W(z)$. This case requires a supplementary condition, namely the codistribution span by $dW, dL/W, \ldots, dL^n/W$ to be of constant rank on $D$ (see [8]). Among other requirements, this geometric condition implies also that $N$ is a manifold, whereas we do not assume here this rather strong assumption.

2) Some other papers deal with extensions of the invariance principle for nonautonomous systems. In two special cases, when the system is either asymptotically autonomous (in [17]) or asymptotically almost periodic (in [13]), the bounded solution tends to the largest pseudo-invariant set in $E$. The problem with these results is that they use the classical Liapunov theorems to obtain the uniform boundedness of the solutions. Thus they require the existence of a strictly positive definite function playing the role of Liapunov function, while here we require only nonnegativeness of the Liapunov-like function. In other approaches an additional auxiliary function is assumed and by means of extra conditions the time in $E$ is controlled (see the results of Salvadori or Matrosov, e.g. in [14]). In a third approach an extra condition on $V$ is considered without any additional condition on the vector field; such an approach is considered in [1].

3) The condition that the restricted dynamics to be uniformly asymptotically stable is necessarily and sufficient. Thus it is a center-manifold-type result where a knowledge about a restricted dynamics to some invariant set implies the same property of the whole dynamics. We point out here that the set $N$ does not need to be a manifold.

4) One could expect that the simple stability for the restricted dynamics would imply the uniform stability for the restricted dynamics. But this is not true as we can see from the following example:
EXAMPLE 1 Consider the following autonomous planar system:

\[
\begin{align*}
\dot{x} &= y^2, \\
y &= -y^3,
\end{align*}
\]  

(4)

The solution of the system is given by \((x,y) \rightarrow (x + \ln(1+y^2 t), \frac{y}{\sqrt{1+y^2 t}})\). It is obvious that the equilibrium is not stable but if we take \(V = y^2\) we have \(\frac{dV}{dt} = -2y^4\) and on the set \(E = N = \{(x,0), x \in \mathbb{R}\}\) the dynamics is trivial stable \(\dot{x} = 0\).

The problem is not the nonisolation of the equilibrium, but the existence of some invariant sets in any neighborhood of the equilibrium;

5) Theorem 2 is the natural generalization of the Invariance Principle to the class of systems considered in this paper. The conclusion of this theorem applies only to bounded trajectories. Thus we have to know a priori which solutions are bounded. Since they are bounded we can extend them indefinitely in positive time. Thus it makes sense to take the limit \(t \to \infty\) in (3). We mention that a more general Invariance Principle can be obtained even under weaker conditions than those from here (see [17]).

The organization of the paper is the following: in the next section we give the proof of these results. In the third section we consider the autonomous case and we present the systemic consequences related to the nonlinear Lyapunov equation and a special type of zero-state detectability. In the fourth section we consider a nonlinear Riccati equation (or Hamilton-Jacobi equation) and we present a result of robust stabilizability by output feedback. The last section contains the conclusions and is followed by the bibliography.

2 Proof of the Main Results

We prove by contradiction the uniform stability of the equilibrium. For this, we construct a \(C^1\)-convergent sequence of solutions that are going away from the origin and whose limit is a trajectory, thus contradicting the hypothesis.

For the uniform asymptotic stability, we prove first that the \(\omega\)-limit set of bounded trajectories are included in \(N\) (implicitly we prove the Invariance Principle - Theorem 2) and then we adapt a classical trick (used for instance in Theorem 34.2 from [6]) that the convergence of trajectories in \(\omega\)-limit set will attract the convergence of the bounded trajectory itself. In both steps we use essentially the time-invariant property of \(f\) restricted to \(E\). In proving the uniform stability we also obtain that the solution can be defined on the whole positive real set (can be completely extended in future).

Theorem 2 (the Invariance Principle) will follow simply from a lemma that we state during the proof of uniformly attractivity.

First we need a lemma:

**Lemma 3** Let \(f\) be a vector field defined on a domain \(D\) and having the properties 1-4 as above. Let \((t_i)\) be a sequence of real numbers and \((w_i)\), \(w_i : [a,b] \to D\) be a sequence of trajectories for the time-translated vector field \(f\) with \(t_i\), i.e. \(w_i(t) = f(t + t_i, w_i(t))\).

If the trajectories are uniformly bounded, i.e. there exists \(M > 0\) such that \(\|w_i\|_{\infty} < M\) for any \(i\), then we can extract a subsequence, denoted also by \((w_i)\), uniformly convergent to a function \(w\) in \(C^1([a,b]; D)\), i.e. \(w_i \to w\) and \(w_i \to w\) both uniformly in \(C^0([a,b]; D)\).\n
**Proof** We apply the Ascoli-Arzelà Lemma twice: first to extract a subsequence such that \((w_i)\) is uniformly convergent and then another subsequence from the second one such that \((w_i)\) is uniformly convergent. Then we obtain that \(\lim_{i} \frac{d}{dx}w_i = \frac{d}{dx}\lim_{i} w_i\).

1. We verify that \((w_i)\) are uniformly bounded and equicontinuous. The uniformly boundedness comes from \(\|w_i\|_{\infty} < M\). The equicontinuity comes from the uniformly boundedness of the first derivative.
Indeed, since \( \| w_t \| \leq M \), the closed ball \( \bar{B}_M \) is compact and \( f(t, \cdot) \) is continuous on \( \bar{B}_M \), there exists a constant \( A \) such that \( \| f(t, x) \| \leq A \), for any \( (t, x) \in \mathbb{R} \times \bar{B}_M \). Then:

\[
\| w_t(t) \| = \| f(t + t_i, w_i(t)) \| \leq A , \text{ for any } i \text{ and } t \in [a, b]
\]

Thus \( (w_t)_i \) is relatively compact and we can extract a subsequence, that we denote also by \( (w_t)_i \), which is uniformly convergent to a function \( w \in C^1([a, b]; D) \).

2. We prove that \( (w_t)_i \) is relatively compact. We have already proved the uniform boundedness \( \| w_t \|_\infty \leq A \). For the equicontinuity we use both the uniform continuity in \( t \) and uniform local Lipschitz continuity in \( x \), of \( f \). Let \( L_M \) be the uniform Lipschitz constant corresponding to the compact set \( \bar{B}_M \). Then:

\[
\| w_t(t_1) - w_t(t_2) \| = \| f(t + t_1, w(t_1)) - f(t + t_2, w(t_2)) \| \leq L_M \| w(t_1) - w(t_2) \|.
\]

Let \( \varepsilon > 0 \) be arbitrary. Then we choose \( \delta_1 \) such that

\[
\| f(s_1, x) - f(s_2, x) \| < \frac{\varepsilon}{2} , \text{ for any } |s_1 - s_2| < \delta_1 \text{ and } x \in \bar{B}_M
\]

On the other hand:

\[
\| f(t + t_2, w(t_1)) - f(t + t_1, w(t_2)) \| \leq L_M \| w(t_1) - w(t_2) \| \leq L_M A |t_1 - t_2|
\]

Then we choose \( \delta = \min\{\delta_1, \frac{\varepsilon}{2L_M A}\} \). Then the left-hand side from the above inequality is also bounded by \( \frac{\varepsilon}{2} \) for any \( t_1, t_2 \) with \( |t_1 - t_2| < \delta \). Thus \( \| w_t(t_1) - w_t(t_2) \| < \frac{\varepsilon}{2} + \frac{\varepsilon}{2} = \varepsilon \), for any \( i \) and \( t_1, t_2 \in [a, b] \), \( |t_1 - t_2| < \delta \).

We can now extract a second subsequence from \( (w_t)_i \) such that \( (w_t)_i \) is also uniformly convergent and this ends the proof of lemma. □

**Proof of Uniform Stability**

Let us assume that the equilibrium is not uniformly stable. Then there exists \( \varepsilon_0 > 0 \) such that for any \( \delta, 0 < \delta < \varepsilon_0 \) there are \( x_0, t \) and \( \Delta > 0 \) such that \( \| x_0 \| < \delta \) and \( \| x(t + \Delta; t, x_0) \| = \varepsilon_0, \| x(t + \tau; t, x_0) \| < \varepsilon_0 \), for \( 0 \leq \tau < \Delta \). We choose \( \varepsilon_0 \) (eventually by shrinking it) such that \( \bar{B}_{\varepsilon_0} \cap N \) is included in the attraction domain of the origin (for the restricted dynamics).

By choosing a sequence \( \{\delta_i\} \) converging to zero we obtain sequences \( \{x_{0i}\}, \{t_i\}_i \) and \( \{\Delta_i\}_i \) such that:

\[
\| x_0i \| \to 0 \text{ and } \| x(t_i + \Delta_i; t_i, x_{0i}) \| = \varepsilon_0
\]

Let \( \delta < \varepsilon_0 \) be such that for any \( z_0 \in B_{\varepsilon_0} \cap N \) we have \( \| x(t; 0, z_0) \| < \frac{\varepsilon_0}{4} \) for any \( t > 0 \) (such a choice for \( \delta \) is possible since the dynamics restricted to \( N \) is stable). Let \( i_0 \) be such that \( \delta_i < \delta \) for \( i > i_0 \). We denote by \( (u_i)_{i > i_0} \) the moments such that \( |x(t_i + u_i; t_i, x_{0i})| = \delta \) and \( \| x(t_i + u_i; t_i, x_{0i}) \| > \delta \) for \( t_i + u_i \). Since the spheres \( S_{\varepsilon_0} \) and \( S_{\delta_0} \) are compact we can extract a subsequence (that we index also by \( i \)) such that both \( x_i = x(t_i + \Delta_i; t_i, x_{0i}) \) and \( y_i = x(t_i + u_i; t_i, x_{0i}) \) are convergent respectively to \( x^*, y^* \); \( x_i \to x^*, y_i \to y^* \), \( |x^*| = \varepsilon_0, |y^*| = \delta \). Since \( V \) is continuously nonincreasing on trajectories and \( \lim V(x_{0i}) = 0 \), we get \( V(x^*) = V(y^*) = 0 \). Therefore \( x^*, y^* \in N \).

Suppose \( \| f(z, t) \| \leq A \) on \( \bar{B}_{\varepsilon_0} \), for some \( A > 0 \). Then one can easily prove that \( \Delta_i - u_i \geq \frac{\varepsilon_0 - \delta}{A} = T_i \), for any \( i > i_0 \) (i.e. the flight time between two spheres of radius \( \delta \) and \( \varepsilon_0 \) has a lower bound).

We define the time-translated vector fields \( f_i(t, x) = f(t + u_i + t_i, x) \) and we denote by \( w_i : [0, T_i] \to \bar{B}_{\varepsilon_0} \) the time-translated solution \( w_i(t) = x(t + t_i + u_i; t_i, x_{0i}) \). Then:

\[
\dot{w}_i(t) = f_i(t, w_i(t)) , \quad 0 \leq t \leq T_i
\]

We apply Lemma 3 and we get a subsequence uniformly convergent to a trajectory \( w_1 : [0, T_1] \to \bar{B}_{\varepsilon_0} \cap N \), such that \( w_1(0) = \lim w_i(0) = y^* \) and \( \| w_1(t) \| > \delta \), for \( 0 < t \leq T_1 \). If \( \| w_1(T_1) \| < \varepsilon_0 \) we obtain that
suc th s a t

\lim k \text{ of the restricted dynamics} \}

THEOREM (Birkhoff's Limit Set Theorem, see \cite{3}) A bounded trajectory approaches its \( \omega \)-limit set: \( \lim_{t \to \infty} d(x(t; t_0, x_0), \Omega(t_0, x_0)) = 0 \), where \( d(p, S) = \inf_{x \in S} \| p - x \| \) is the distance between the point \( p \) and the set \( S \).

LEMMA 5 (Barbálat's Lemma, see \cite{2}) If \( g : [t_0, \infty) \to \mathbb{R} \) is an uniformly continuous function such that the following limit exists and is finite, \( \lim_{t \to \infty} \int_{t_0}^{t} g(\tau) \, d\tau \), then there exists the limit and it is zero: \( \lim_{t \to \infty} g(t) = 0 \).

Proof of Uniform Attractivity
We already know that \( \bar{z} = 0 \) is uniformly stable. What we have to prove is the uniform attractivity.

Let \( \varepsilon_0 \) be chosen with the following properties: for any \( t_0 \) and \( x_0 \in D \cap B_{\varepsilon_0} \), the positive trajectory \( x(t; t_0, x_0) \) is bounded by \( \varepsilon_1 \) (i.e. \( x(t; t_0, x_0) \in B_{\varepsilon_1} \) for any \( t_1 \) and \( x_1 \in D \cap B_{\varepsilon_1} \), the trajectory \( x(t; t_1, x_1) \), \( t > t_1 \), is bounded by some \( M \), and for any \( x_2 \in N \cap B_{\varepsilon_1} \), the trajectory \( x(t; t_0, x_2) \) tends to the origin \( \lim_{t \to \infty} x(t; t_0, x_2) = 0 \). We are going to prove that \( \lim_{t \to \infty} x(t; t_0, x_0) = 0 \).

Let us consider the \( \omega \)-limit set \( \Omega(t_0, x_0) \). It is enough to prove that \( \Omega(t_0, x_0) = \{0\} \), because of Birkhoff's Limit Set Theorem.

Let \( x^* \in \Omega(t_0, x_0) \) and suppose \( x^* \neq 0 \). Let us denote by \( x(t) = x(t; t_0, x_0) \) and \( g(t) = \nabla V(x(t)) \cdot f(t, x(t)) \). Since the solution is continuous and bounded, it is \( g(t) \). On the other hand

\[
V(x(t)) = V(x_0) + \int_{t_0}^{t} g(\tau) \, d\tau
\]

Since \( \dot{x}(t) = f(t, x(t)) \) and \( x(t) \) is bounded we obtain that it is also uniformly continuous. Thus \( g(t) \) is also uniformly continuous (recall we have assumed \( f(\cdot, x) \) is uniformly continuous in \( t \)). Let \( (t_k) \) be a sequence that renders \( x^* \) a \( \omega \)-limit point. Then \( \lim_{k} V(x(t_k)) = V(\lim_{k} x(t_k)) = V(x^*) \). Since \( V(x(t)) \) is a decreasing function bounded below, there exists the limit: \( \lim_{t \to \infty} V(x(t)) = V(x^*) \). Now, applying Barbálat's Lemma we obtain \( \lim_{t \to \infty} g(t) = 0 \) or \( W(x^*) = 0 \). Thus \( \Omega(t_0, x_0) \subseteq E \), the kernel of \( W \).
In this point we need a result about the behaviour of solutions starting at $x^*$. We mention that the following lemma is a consequence of Theorem 3 from [17]. But, since we are under stronger conditions, we have found a simpler proof that we are going to present here (our conditions are stronger because we need to obtain uniform stability and consequently boundedness of the solutions when Lyapunov function is only positive semidefinite, which overall means a weaker condition).

**Lemma 6** The positive trajectory starting at $x^*$ is included in $E$ and thus the $Ω$-limit set is a positive invariant set included in $N$.

**Proof**

Let $τ > 0$ be an arbitrary time interval. Let $(t_k)_k$ be the sequence of times that renders $x^*$ a $ω$-limit point for the trajectory $z(t) = z(t; t_0, x_0)$. Then, if we denote by $z_k = z(t_k)$ we have $lim_k z_k = x^*$.

Consider the following sequence of functions:

$$w_k : [0, τ] → D , \quad w_k(t) = z(t + t_k; t_k, x^*)$$

We have chosen $x_0, t_0$ such that all these functions are bounded by $M$, i.e. $\|w_k\|_∞ < M$. We have $w_k(0) = x^*$ and $V(w_k(t)) ≤ V(x^*)$. Let us denote by $y^t_k = z(t + t_k)$, for any $0 ≤ t ≤ τ$, and let $L_M$ be the Lipschitz constant of $f$ on the compact $B_M$.

Then:

$$\|y^t_k - w_k(t)\| ≤ e^{L_M t} \|z_k - x^*\|$$

and, since $lim_k z_k = x^*$ we get $lim_k \|y^t_k - w_k(t)\| = 0$. On a hand, since $V(z^*) = lim_k →∞ V(z(t))$ and $V$ is nonincreasing on trajectories we have $V(y^t_k) > V(x^*)$ and also $lim_k \|y^t_k - w_k(t)\| = lim_k \|V(w_k(t))\|$. On the other hand, since $(w_k)_k$ are uniformly bounded we apply Lemma 3 and we obtain a subsequence uniformly convergent to a function $w ∈ C^1([0, τ]; D ∪ B_M)$. Obviously $V(w(t)) = V(x^*)$ for any $0 ≤ t ≤ τ$. Thus $W(w(t)) = 0$ and $w(t) ∈ E$. On the other hand, since $f$ is continuous in $(t, x)$ we obtain that $w$ is an integral curve of $f$, i.e. $w(t) = f(t, w(t))$, for $0 ≤ t ≤ τ$ and any $t_*$. In particular, for $t_0 = t_k$ we get $w(t)$ is a solution of the same equation as $w(t)$ and $w(0) = w(0) = x^*$. By the uniqueness of the solution they must coincide. Then $z(t + t_k; t_k, x^*) ∈ E$ for $0 ≤ t ≤ τ$. But $τ$ was arbitrary; thus $z(t; t_0, x^*) ∈ E$ for any $t$ and then $x^* ∈ N$. □

Since the trajectory starting at $x^*$ is included in $N$, it should converge to the origin (the equilibrium point). Let us denote by $ε = \frac{\|x^*\|}{2}$. From uniform stability there exists a $δ > 0$ such that for any $z ∈ D$, $\|z\| < δ$ implies $\|z(t_1; t_1, z)\| < ε$, for any $t_1, t_2 > t_1$. Let $Δt$ be a time interval such that $\|y(t_0, x^*)\| < \frac{ε}{2}$ for any $t > Δt$. We consider the compact set $C$, the $\frac{ε}{2}$-neighborhood of the compact curve $Γ = \{z(t_0, x^*)\}$:

$$C = \{z ∈ D | d(z, Γ) ≤ \frac{δ}{2}\} = \bigcup_{t ∈ [t_0, t_1]} B_{\frac{ε}{2}}(x(t_0, x^*))$$

which is the union of the closed balls centered at $x(t_0, x^*)$ and of radius $\frac{ε}{2}$. We set $δ_1 = \frac{ε}{2}exp(-L_C Δt)$ where $L_C$ is the uniform Lipschitz constant of $f$ on the compact set $C$. Since the solution is uniformly Lipschitz with respect to the initial point $x_0$ we have that for any $t_1 ∈ R$ and $x_1$ such that $\|x_1 - x^*\| < δ_1$ we get:

$$\|z(t_1 + Δt; t_1, x_1) - z(Δt; 0, x^*)\| < \frac{δ}{2}$$

and then $\|z(t_1 + Δt; t_1, x_1)\| < δ$. Furthermore, from the choice of $δ$ we obtain that $\|z(t_1 + τ; t_1, x_1)\| < ε$, for any $τ > Δt$ or $\|z(t_1 + τ; t_1, x_1) - x^*\| > ε$, for any $τ > Δt$.

Now we pick a $t_n$ such that $\|z(t_n; t_0, x_0) - x^*\| < δ_1$. Then, from the above discussion $\|z(t_n + τ; t_0, x_0) - x^*\| > ε$, for any $τ > Δt$ which contradicts the limit $lim_k z(t_k; t_0, x_0) = x^*$. This contradiction comes from the hypothesis that $x^* ≠ 0$. Thus $Ω(t_0, x_0) = \{0\}$ and now the proof is complete. □

**Proof of Theorem 2 (The Invariance Principle)**
If \( x(t; t_0, x_0) \) is a bounded trajectory then, from Birkhoff’s Limit Set Theorem it approaches its \( \omega \)-limit set. On one hand we can use Barbalat’s Lemma and prove that \( W \) vanishes on \( \omega \)-limit set of bounded trajectories. On the other hand, as we have proved in Lemma 6, the \( \omega \)-limit set is invariant and included in \( N \). Thus the bounded trajectory approaches the set \( N \). □

3 The Autonomous Case: Consequences in Nonlinear Control Theory

Consider the following inputless nonlinear control system:

\[
S \begin{cases}
\dot{x} = f(x) \\
y = h(x)
\end{cases}, \quad x \in D \subset \mathbb{R}^n \quad y \in \mathbb{R}^p
\]

such that \( f(0) = 0 \), \( h(0) = 0 \) and \( D \) a neighborhood of the origin. Suppose \( f \) is local Lipschitz continuous and \( h \) continuous on \( D \). Then denote by \( x(t; x_0) \) the flow generated by \( f \) on \( D \) (i.e. the solution of \( \dot{x} = f(x) \), \( x(0) = x_0 \)), by \( E = \ker h = \{ x \in D | h(x) = 0 \} \), the kernel of \( h \) and by \( N \) the maximal positive invariant set included in \( E \), i.e. the set \( N = \{ \tilde{x} \in D | h(x(t, \tilde{x})) = 0 \text{ for any } t \geq 0 \text{ such that } x(t, \tilde{x}) \text{ has sense} \} \).

We present two definitions for the notion of detectability of (5). The first one has been used by many authors in the last time (see for instance [9]).

**Definition** The pair \((h, f)\) is called zero-state detectable if \( \tilde{x} = 0 \) is an attractive point for the dynamics restricted to \( N \), i.e. there exists an \( \varepsilon_0 > 0 \) such that for any \( x_0 \in N \), \( \| x_0 \| < \varepsilon_0 \) there exists the limit \( \lim_{t \to \infty} x(t, x_0) = 0 \).

**Definition** The pair \((h, f)\) is called strong zero-state detectable if \( \tilde{x} = 0 \) is an asymptotically stable equilibrium point for the dynamics restricted to \( N \), i.e. it is weak zero-state detectable and for some \( \varepsilon_0 \) and for any \( x_0 \in N \) with \( \| x_0 \| < \varepsilon_0 \) there exists the limit \( \lim_{t \to \infty} x(t, x_0) = 0 \).

We see that strong z.s.d. implies z.s.d., but obvious the converse is not true.

In this framework, as a consequence of the main result we can state the following theorem:

**Theorem 7** For the inputless nonlinear control system (5) with \( f \) local Lipschitz continuous and \( h \) continuous, consider the following nonlinear Liapunov equation:

\[
\nabla V \cdot f + \| h \|^q = 0
\]

or the following nonlinear Liapunov inequality:

\[
\nabla V \cdot f + \| h \|^q \leq 0
\]

for some \( q > 0 \). Suppose there exists a positive semidefinite solution of (6) or (7) of class \( C^1 \) defined on \( D \) such that \( V(0) = 0 \).

Then the pair \((h, f)\) is strong zero-state detectable if and only if \( \tilde{x} = 0 \) is an asymptotically stable equilibrium for the dynamics (5). □

An example where this theorem is applied is given below:

**Example 2** Consider the dynamics:

\[
\begin{align*}
\dot{x}_1 &= -x_1^3 + \Psi(x_2) \\
\dot{x}_2 &= -x_2^3
\end{align*}, \quad (x_1, x_2) \in \mathbb{R}^2
\]

where \( \Psi : \mathbb{R} \to \mathbb{R} \) is local Lipschitz continuous, \( \Psi(0) = 0 \) and there exist constants \( a > 0, b \geq 1 \) such that:

\[
|\Psi(x)| \leq a|x|^b, \quad \forall x
\]
If we choose as output function \( h(x) = x_2^2 \) we see that the pair \((h, f)\) is strong zero-state detectable; indeed, the set \( E = \{x \in \mathbb{R}^2 | h(x) = 0\} = \{(x_1, 0) | x_1 \in \mathbb{R}\} \) and the dynamics restricted to \( E \) is \( \dot{x}_1 = -x_1^3 \) which is asymptotically stable.

Now, if we choose:

\[
V(x) = \frac{x_2^2}{2}
\]

we have \( \dot{V} = -x_1^2 \) and thus \( V \) is a solution of the Liapunov equation (6) with \( q = 2 \). Then, the equilibrium is asymptotically stable, as a consequence of the theorem 7.

On the other hand we see that for \( x_2 \) we have an explicit formula for the solution:

\[
x_2(t) = \frac{x_{20}}{\sqrt{2(1 + x_{10}^2 t)}}
\]

and then we have: \( |\psi(x_2(t))| \leq C(1 + Bt)^{-1/2} \) for some \( B, C > 0 \) and any \( t \geq 0 \). Now the asymptotic stability follows as a consequence of Theorem 68.2 from [6] (stability under perturbation).

### 4 An Application in Robust Stabilizability

We present here, as an application, a robust stabilizability result for a nonlinear affine control system. In fact it is an absolute stability result about a particular situation. More general results about absolute stability for nonlinear affine control system will appear in a forthcoming paper. We base our approach on the existence of a positive semidefinite solution of some Hamilton-Jacobi equation or inequality.

Discussions about solutions of this type of equation may be found in [15].

Consider the following Single Input - Single Output control system:

\[
\begin{align*}
\dot{x} &= f(x) + g(x)u \\
y &= h(x)
\end{align*}
\]

where \( f \) and \( g \) are local Lipschitz continuous vector fields on a domain \( D \) including the origin, \( h \) is a local Lipschitz real-valued function on \( D \), and \( f(0) = 0, h(0) = 0 \). Consider also a local Lipschitz output feedback:

\[ \varphi : \mathbb{R} \to \mathbb{R}, \quad \varphi(0) = 0 \]

We define now two classes of perturbations associated to this feedback. Let \( a > 0 \) be a positive real number. The first class contains time-invariant perturbations:

\[ P_1 = \{ p : \mathbb{R} \to \mathbb{R}, p \text{ is local Lipschitz, } p(0) = 0 \text{ and } |p(y)| < a |\varphi(y)|, \forall y \neq 0 \} \]

while the second class is composed by time-varying perturbations:

\[ P_2 = \{ p : \mathbb{R} \times \mathbb{R} \to \mathbb{R}, p(y, t) \text{ is local Lipschitz in } y \text{ for } t \text{ fixed and uniformly continuous in } t \text{ for any } y \text{ fixed, } p(0, t) \equiv 0 \text{ and there exists } \varepsilon > 0 \text{ such that } |p(y, t)| < (a - \varepsilon) |\varphi(y)|, \forall y \neq 0, t \} \]

Now we can define more precisely the concept of robust stability:

**Definition** We say the feedback (10) robustly stabilizes the system (9) with respect to the class \( P_1 \cup P_2 \) if for any perturbation \( p \in P_1 \cup P_2 \) the closed-loop with the perturbed feedback \( \varphi + p \) has an asymptotically stable equilibrium at the origin.

In other words, we require that the origin to be asymptotically stable for the dynamics:

\[
\dot{x} = f(x) + g(x)(\varphi(h(x)) + p(h(x), t))
\]

for any \( p \in P_1 \cup P_2 \). Since the null function belongs to \( P_1 \), the feedback \( \varphi \) itself must stabilize the closed-loop too.

With these preparations we can state the result:
THEOREM 8 Consider the nonlinear affine control system (9) and the feedback (10). Suppose the pair \((h,f)\) is strong zero-state detectable and suppose the following Hamilton-Jacobi equation:
\[
\nabla V \cdot f + \left( \frac{1}{2} \nabla V \cdot g + \varphi \circ h \right)^2 - (1 - a^2)(\varphi \circ h)^2 = 0 , \quad V(0) = 0
\]

or inequality:
\[
\nabla V \cdot f + \left( \frac{1}{2} \nabla V \cdot g + \varphi \circ h \right)^2 - (1 - a^2)(\varphi \circ h)^2 \leq 0 , \quad V(0) = 0
\]

has a positive semidefinite solution \(V\) of class \(C^1\) on \(D\).

Then the feedback \(\varphi\) robustly stabilizes the system (9) with respect to the class \(P_1 \cup P_2\).

Proof

Let us consider a perturbation \(p \in P_1 \cup P_2\). Then, the closed-loop dynamics is given by (11). We compute the time derivative of the solution \(V\) of (12) with respect to this dynamics:
\[
\frac{dV}{dt} = \nabla V \cdot f(x) + \nabla V \cdot g(x)(\varphi(h(x)) + p(h(x),t))
\]

After a few algebraic manipulations we get:
\[
\frac{dV}{dt} \leq - (\frac{1}{2} \nabla V \cdot g - p \circ h)^2 + (p \circ h)^2 - a^2(\varphi \circ h)^2
\]

Now, for \(p \in P_1\), \(\frac{dV}{dt}\) is time-independent and we may take for instance:
\[
W(x) = (p(h(x)))^2 - a^2(\varphi(h(x)))^2 \leq 0
\]

For \(p \in P_2\), \(\frac{dV}{dt}\) is time-dependent and we define:
\[
W(x) = -(2ae - \varepsilon^2)(\varphi(h(x)))^2 \leq 0
\]

Either a case or the other, we obtain (recall the definitions of \(P_1\) and \(P_2\)):
\[
\frac{dV}{dt} \leq W(x) \leq 0
\]

The kernel-set of \(W\) is given by:
\[
E = \{x \in D \mid W(x) = 0\} = \{x \in D \mid h(x) = 0\}
\]

We see that the closed-loop dynamics (11) restricted to \(E\) is simply given by \(\dot{x} = f(x)\) and is time-independent. Moreover, since we have supposed \((h,f)\) is strong zero-state detectable, it follows that the restricted dynamics to the maximal positive invariant set in \(E\) has an asymptotically stable equilibrium at the origin. Now, applying Theorem 1, the result follows. □

Let us consider now an example:

EXAMPLE 3 Consider the following planar nonlinear control system:
\[
\begin{align*}
\dot{x}_1 &= -x_1^2 + u \\
\dot{x}_2 &= -x_2^3 \\
y &= x_2^3
\end{align*}
\]

(14)

We are interested to find how robust the feedback \(\varphi(y) = y\) is, i.e. how large we can choose \(a\) such that \(\varphi\) robustly stabilizes the system (14) with respect to the class \(P_1 \cup P_2\).
The Hamilton-Jacobi equation (12) takes the form:

\[-x_1^2 \frac{\partial V}{\partial x_1} - x_2^3 \frac{\partial V}{\partial x_2} + \left( \frac{1}{2} \frac{\partial V}{\partial x_1} + x_2^2 \right)^2 - (1 - a^2)x_1^2 = 0\]

or:

\[-x_1^2 \frac{\partial V}{\partial x_1} - x_2^3 \frac{\partial V}{\partial x_2} + \frac{1}{4} \left( \frac{\partial V}{\partial x_1} \right)^2 + x_2 \frac{\partial V}{\partial x_1} + a^2 x_2^6 = 0\]

A solution of this equation is:

\[V(x_1, x_2) = \frac{a^2}{4} x_2^4\]

For any \(a > 0\) it is positive semidefinite and the system (14) is strong zero-state detectable. Thus, as a consequence of theorem 8, we can choose an arbitrary large such that \(\varphi\) robustly stabilizes the system (14) with respect to the class \(P_1 \cup P_2\).

On the other hand, for any feedback \(\Phi\), local Lipschitz and:

\[|\Phi(y)| \leq a|y|, \text{ for some } a > 0\]

we have seen in the previous example that the closed-loop has an asymptotically stable equilibrium at the origin.

5 Conclusions

In this paper we study an extension of Barbashin-Krasovski-LaSalle and Invariance Principle to a class of time-varying dynamical systems. We impose two type of conditions on the vector field: one is regularity (we require uniformly continuity with respect to \(t\) and uniformly local Lipschitz continuity and boundedness with respect to \(x\)); the other condition requires the vector field to be time-invariant on the zero-set \(E\) of an auxiliary function. In this setting we find that the asymptotic behaviour of the dynamics restricted to the largest positive invariant set in \(E\) determines the asymptotic stability character of the full dynamics.

Then we study two applications in control theory. The first application concerns the notion of detectability. We give another definition for this notion, called strong zero-state detectability and we show how the existence of a positive semidefinite solution of the Lyapunov equation or inequality is related to the asymptotic stability of the equilibrium. We obtain a nonlinear equivalent of the linear well-known result: if the pair \((C, A)\) is detectable and there exists a positive solution \(P \geq 0\) of the Lyapunov algebraic equation \(A^T P + PA + C^T C = 0\), then the matrix \(A\) has all eigenvalues with negative real part.

The second application is on the problem of robust stabilizability. We give sufficient conditions such that a given feedback robustly stabilizes the closed-loop with respect to two sector classes of perturbations (time-invariant and time-varying). The condition is formulated in terms of the existence of a positive solution of some Hamilton-Jacobi equation or inequality.

This last application opens the problem of absolute stability for nonlinear affine control systems, that will be considered in a forthcoming paper.
