

# 111, section 8.6 Applications of the Normal Distribution

notes by Tim Pilachowski

A probability density function  $f(x)$  for a continuous random variable has two necessary characteristics.

1.  $f(x) \geq 0$  for all values of  $x$  in its domain [since all probabilities and therefore “areas under the curve” are zero or positive]
2. The area under the curve over the entire domain = 1 [since the sum of all probabilities = 1]

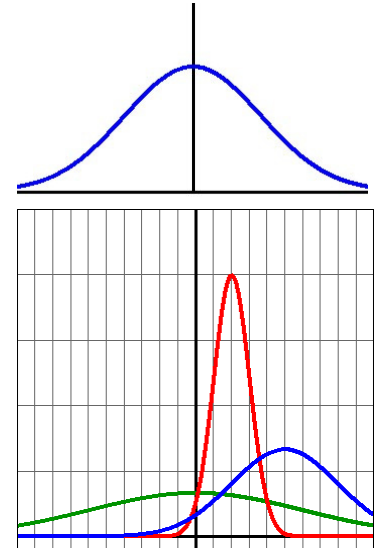

The graph of a probability density function has a very useful characteristic: area under the probability density curve between  $a$  and  $b = P[a \leq X \leq b]$ .

An often-useful probability density function is the standardized normal density function, which graphs as the familiar bell-shaped curve, with  $E(X) = \mu = 0$  and standard deviation =  $\sigma = 1$ .

In the early Examples of section 8.5, we worked with various values for the standardized normal random variable  $Z$  and were able to get our answers by going directly to the normal distribution table.

Rather than approximate values for *every possible* normal density function, the common practice is to convert everything to a standard normal distribution and use the same normal distribution table over and over.

The  $z$ -score formula for converting a normal random variable  $X$  into the standardized normal random variable  $Z$  is  $Z = \frac{X - \mu}{\sigma}$ .

Example A: (source <http://www.cdc.gov/nchs/data/ad/ad347.pdf>) “During the last 2 decades the prevalence of obesity and overweight has increased in the United States. This is in part due to a shift in the distribution of BMI (weight in kilograms divided by height in meters squared) of the entire population...Between the early 1960s and 1999–2002 mean BMI for men 20–74 years of age increased from just over 25 to almost 28. Similarly, for women mean BMI increased from almost 25 to just over 28.” Distribution is approximately normal. Using data from Table 10 of this report, in 1999–2002 mean BMI for adults 20 years and over = 27.95, with a standard deviation of 0.15.

- a) Find the probability that an adult selected at random has a BMI between 27.7 and 28.3
- b) Find the probability that an adult selected at random has a BMI greater than 28.3
- c) Find the BMI value that marks the top 30%

answers: 0.9426; 0.0099; 28.03

Example B: Distribution of SAT scores is approximately normal. In 2010 mean score for the three sections of the SAT = 1509, with a standard deviation of 339.

(source: *College Entrance Examination Board, College-Bound Seniors: Total Group Profile [National] Report, 1966-67 through 2009-10*, retrieved from <http://professionals.collegeboard.com/data-reports-research/sat/cb-seniors-2010>.) “College-Bound Seniors presents data for high school graduates in the year 2010 who participated in the SAT Program. Students are counted only once, no matter how often they tested, and only their latest scores and most recent SAT Questionnaire responses are summarized.” “The data in this report includes students in the class of 2010 who took the SAT through March 2010. Seniors who tested for the first time in May and June are not included in the detailed analyses. In total, over 1.59 million college-bound seniors in the class of 2010 took the SAT.”

a) Find the probability that a student selected at random has an SAT score between 1200 and 1800.

answer: 0.6237

b) Find the probability that a student selected at random has an SAT score greater than 1950. answer: 0.0968

c) Distribution of ACT scores is approximately normal. In 2010 mean score for the ACT = 22.6, with a standard deviation of 4.3. Which is better, a score of 1950 on the SAT or a score of 28.4 on the ACT?

(source: *Usefulness of High School Average and ACT Scores in Making College Admission Decisions*, retrieved from [www.act.org/research/researchers/reports/pdf/ACT\\_RR2010-2.pdf](http://www.act.org/research/researchers/reports/pdf/ACT_RR2010-2.pdf).) answer: 28.4 on the ACT

Section 8.6 now takes us back to binomial probability distributions. The text does a good job of presenting the theory behind using the normal distribution table to approximate probabilities for a binomial distribution, so I won't duplicate it here.

Recall that the mean of a binomial distribution is  $\mu = np$  and the standard deviation is  $\sigma = \sqrt{npq} = \sqrt{np(1-p)}$ .

We need to note that using the normal distribution table to approximate a binomial distribution is not always appropriate—the fit isn't close enough for small values of  $n$  or large values of  $p$ . The rule of thumb is that both  $np$  and  $nq$  must be greater than 5.

Example C. A Math 220 class, taught in the Fall of 2010 at UMCP, had the grade distribution pictured to the right. Define success as  $X =$  earning an A, B or C.

$p =$

For  $n = 25$ ,  $np =$

and  $nq = n(1 - p) =$

For  $n = 200$ ,  $np =$

and  $nq = n(1 - p) =$

For  $n = 200$ , find a)  $P(X = 166)$ , b)  $P(166 \leq X < 170)$ , c)  $P(X > 170)$ .

answers: 0.0718, 0.2813, 0.1977

Example D. From past experience, Shockingly Good Inc., knows that the probability of producing a defective spark plug is 0.02. Let random variable  $X$  be the number of defective spark plugs in a shipment of 800. Use a normal approximation to a binomial distribution to find a)  $P(X \leq 20)$ , b)  $P(14 < X \leq 20)$ ,  $P(X \geq 20)$ .

answers: 0.8729, 0.5209, 0.1894
