March 31, 2025

## Abstract

The blind image deconvolution is a challenging, highly ill-posed nonlinear inverse problem. We introduce a Multiscale Hierarchical Decomposition Method (MHDM) that is iteratively solving variational problems with adaptive data and regularization parameters, towards obtaining finer and finer details of the unknown kernel and image. We establish convergence of the residual in the noise-free data case, and then in the noisy data case when the algorithm is stopped early by means of a discrepancy principle. Fractional Sobolev norms are employed as regularizers for both kernel and image, with the advantage of computing the minimizers explicitly in a pointwise manner. In order to break the notorious symmetry occurring during each minimization step, we enforce a positivity constraint on the Fourier transform of the kernels. Numerical comparisons with a single-step variational method and a non-blind MHDM show that our approach produces comparable results, while less laborious parameter tuning is necessary at the price of more computations. Additionally, the scale decomposition of both reconstructed kernel and image provides a meaningful interpretation of the involved iteration steps.

## 1 Introduction

An important problem in image processing is the image restoration one, which aims to remove noise and blur from a degraded image. More precisely, assume that  $f$  is a given blurry-noisy image, with the degradation model  $f = k * u + n^\delta$ , where  $u$  is the true image to be recovered,  $k$  is a blurring kernel, and  $n^\delta$  denotes some kind of additive noise. There are plenty of statistical, variational and partial differential equation strategies to approach the problem. A classical variational model for this linear ill-posed problem under the assumption of normally distributed noise is

$$\min_u \{ \|f - k * u\|_{L^2(\mathbb{R}^2)}^2 + \lambda \text{Reg}(u) \}, \quad (1)$$

where  $\lambda > 0$  is the regularization parameter that should balance stability and accuracy in the solution reconstruction, and  $\text{Reg}$  stands for a penalty that promotes desired features for the recovered image, such as total variation in case of piecewise constant structures (see [33]). However, recovering both  $u$  and  $k$  from  $f$ , knowing little information about the degradation, is a highly ill-posed nonlinear inverse problem, so-called blind deconvolution. For instance, it occurs in the context of astronomical imaging [18, 28, 31], microscopy [20, 10, 41] or movement correction in digital photography [7, 14, 23]. As above, one way to alleviate the difficulty in solving this problem is to use the variational approach with regularization.

Seminal work in [40] and [9] proposed blind deconvolution models using joint minimizations of the form

$$\min_{u,k} \{ \|f - k * u\|_{L^2(\mathbb{R}^2)}^2 + \lambda \text{Reg}(u) + \mu \text{Reg}(k) \}, \quad (2)$$

which can be solved using alternating minimization and two coupled Euler-Lagrange equations. Here  $\text{Reg}$  denotes some generic regularization functional, which might be chosen differently for  $u$  and  $k$ . In [40], the regularization terms were both Sobolev  $H^1$  norms, while in [9], they were the total variation for  $u$ , and total variation or the Sobolev norm  $H^1$  for  $k$ . Still, the joint regularization problem, as is, involves too much symmetry between the unknowns  $u$  and  $k$  and thus, non-uniqueness issues appear. Note that, under some assumptions, if  $(\tilde{u}, \tilde{k})$  is a joint minimizer in (2), then also  $(m\tilde{k}, \frac{\tilde{u}}{m})$  is a joint minimizer, for some constant  $m$ . A detailed analysis of this difficulty and useful ideas are presented in the book [8, Chapter 5]. For instance, additional constraints can be included for better restoration:  $k \geq 0$ ,  $\int_{\mathbb{R}^2} k(x) dx = 1$ , or  $k$

radially symmetric, to break the symmetry of the problem. Regarding possible regularization functionals, we mention the works [38, 35, 22] which employ sparsity promoting functionals based on  $\ell^p$  (quasi)norms, as well as [13, 34] where generalizations of the total variation are used as penalty terms for the image. Note that regularization of both the image and the kernel seems necessary, since omitting a penalty on the latter might lead to inadequate results, cf [29]. Beside the variational approaches, two stage methods [12, 19], as well as a multitude of (statistically motivated) iterative algorithms [17, 25, 15, 1, 24] have been proposed. More recently, the application of machine learning methods to blind deconvolution has become popular [32, 3, 16]. However, in this work, we focus on a different technique, called multiscale hierarchical decomposition of images (MHDM), introduced in [36, 37], that favors gradual reconstruction of image features at increasingly small scales. More precisely, in that work for (denoising and) non-blind deconvolution, it was emphasized that separating cartoon and texture in images is highly dependent on the scale  $\lambda$  from (1), in the sense that details in an image (usually part of the texture) can be seen as a cartoon at a refined scale, such as  $\lambda/2$ .

In [36, 37], one starts with getting a minimizer  $u_0$  of (1), then continues with iteratively solving similar minimization problems which aim at extracting more detailed information from the current data  $f - k * (u_0 + \dots + u_{i-1})$  by using different scale parameters  $\lambda$  at every step. Thus, one obtains a sequence of minimizers  $u_0, u_1, \dots$ , via

$$u_i \in \arg \min_u \{ \|f - k * (u + u_0 + \dots + u_{i-1})\|_{L^2(\mathbb{R}^2)}^2 + \lambda_i \text{Reg}(u) \},$$

such that  $f \approx k * (u_0 + u_1 + \dots + u_n)$ . Energy estimates and applications to non-blind deconvolution, scale separation, and registration are shown in [37, 27]. Moreover, error estimates for the data-fitting term, and stopping index rules are provided in recent works [26, 21, 2], which also clearly point out that the MHDM merits are at least twofold. Namely, it provides fine recoveries of images with multiscale features that are otherwise not obtainable by single step variational models, and it is pretty robust with respect to the choice of the initial parameter  $\lambda$  (and of parameters involved in the computational procedures), thus avoiding the burden of choosing it appropriately when performing only one step in (1). To be fair though on the comparison, note that more computations are involved when using MHDM.

To benefit from these effects, we are interested to extend the MHDM to the more complex problem of blind deconvolution. Clearly, we do not have

$$(k_0 + k_1 + \dots + k_n) * (u_0 + u_1 + \dots + u_n) = k_0 * u_0 + k_1 * u_1 + \dots + k_n * u_n,$$

as we would try to “blindly” apply the hierarchical decomposition method to blind deconvolution. Instead, we introduce an appropriate procedure that provides reconstructions of the kernel and of the true image of the form in the left-hand side above. Let us first specify the notation. We consider the observed blurred and noisy image  $f^\delta$  given by

$$f^\delta = K^\dagger * U^\dagger + n^\delta, \quad (3)$$

where  $U^\dagger$  is the true image,  $K^\dagger$  a blurring kernel, and  $n^\delta$  some additive noise. We therefore assume  $U^\dagger, K^\dagger \in L^2(\mathbb{R}^2)$  for the convolution to be well-defined. Here  $L^2(\mathbb{R}^2)$  denotes the space of real-valued, square integrable function on  $\mathbb{R}^2$ . The space of complex valued, square integrable functions will be denoted by  $L^2(\mathbb{R}^2, \mathbb{C})$ . Let  $J_1, J_2 : L^2(\mathbb{R}^2) \rightarrow \mathbb{R} \cup \{\infty\}$  be proper, lower semicontinuous, convex and non-negative functionals. The aim is to reconstruct  $U^\dagger$  and  $K^\dagger$  from the observation  $f^\delta$  by adapting the MHDM to problem (3). That is, we would like to decompose  $U^\dagger$  and  $K^\dagger$  as sums

$$U^\dagger = \sum_{i=0}^{\infty} u_i, \quad K^\dagger = \sum_{i=0}^{\infty} k_i, \quad (4)$$

where each component  $k_i$  and  $u_i$  contains features of  $K^\dagger$  and  $U^\dagger$ , respectively, at a different scale. Let us point out that the additive decomposition of both convoluted functions has a multitude of potential applications, even beyond image deblurring. For instance, the sequence of iterates  $k_i$  contains information that could be used in the classification or learning of point-spread-functions in real applications, such as in remote sensing and atmospheric sciences, where point-spread-functions are not known and have complicated features and oscillations at different scales (see for instance the GeoSTAR PSF in [39]). Furthermore, such decompositions could be applied to parameter identification problems with an unknown differential operator. The kernel decomposition in such problems corresponds to an additive decomposition of the problem’s Green-function. Hence, the scale decomposition of this function can be interpreted as different physical effects. Those components corresponding to coarser scales describe the overall model, while the finer scales act as its refinements.

Therefore, we proceed as follows. Let  $(\lambda_n)_{n \in \mathbb{N}_0}, (\mu_n)_{n \in \mathbb{N}_0}$  be decreasing sequences of positive real numbers. Additionally, let  $\Phi : (L^2(\mathbb{R}^2) \times L^2(\mathbb{R}^2)) \times L^2(\mathbb{R}^2) \rightarrow [0, \infty)$  be a measure of similarity between  $K * U$  and an image  $f$ , which satisfies  $\Phi(K, U, f) = 0$  for all  $K, U$  with  $K * U = f$ . We consider data fidelity terms for noisy observations that have the form

$$\Phi(K, U, f^\delta) = \|f^\delta - K * U\|_{L^2}^2 + \delta_{S_1}(U) + \delta_{S_2}(K). \quad (5)$$

Here

$$\delta_S(z) = \begin{cases} 0 & \text{if } z \in S \\ \infty & \text{if } z \notin S \end{cases}$$

denotes the indicator function of a convex set  $S$  and is used to encode additional assumptions such as positivity of the kernel or constraints on the means of images and kernels.

We compute the initial iterates as

$$(u_0, k_0) \in \arg \min_{u, k \in L^2(\mathbb{R}^2)} \Phi(k, u, f^\delta) + \lambda_0 J_1(u) + \mu_0 J_2(k). \quad (6)$$

Next, set  $U_0 = u_0$ ,  $K_0 = k_0$  and determine the increments  $u_1, k_1$  such that  $U_1 = U_0 + u_1$  and  $K_1 = K_0 + k_1$  via

$$(u_1, k_1) \in \arg \min_{u, k \in L^2(\mathbb{R}^2)} \left\{ \begin{aligned} & \|f^\delta - (k + K_0) * (u + U_0)\|_{L^2}^2 \\ & + \delta_{S_1}(u + U_0) + \delta_{S_2}(k + K_0) + \lambda_1 J_1(u) + \mu_1 J_2(k) \end{aligned} \right\}.$$

Thus, we iterate for  $n \in \mathbb{N}_0$ ,

$$(u_{n+1}, k_{n+1}) \in \arg \min_{u, k \in L^2(\mathbb{R}^2)} \Phi(k + K_n, u + U_n, f^\delta) + \lambda_{n+1} J_1(u) + \mu_{n+1} J_2(k), \quad (7)$$

that is,

$$(u_{n+1}, k_{n+1}) \in \arg \min_{u, k \in L^2(\mathbb{R}^2)} \left\{ \begin{aligned} & \|f^\delta - (k + K_n) * (u + U_n)\|_{L^2}^2 \\ & + \delta_{S_1}(u + U_n) + \delta_{S_2}(k + K_n) + \lambda_{n+1} J_1(u) + \mu_{n+1} J_2(k) \end{aligned} \right\},$$

and set  $U_{n+1} = u_{n+1} + U_n$ ,  $K_{n+1} = k_{n+1} + K_n$ . Note that (7) can also be formulated as

$$(U_{n+1}, K_{n+1}) \in \arg \min_{U, K \in L^2(\mathbb{R}^2)} \Phi(K, U, f^\delta) + \lambda_{n+1} J_1(U - U_n) + \mu_{n+1} J_2(K - K_n). \quad (8)$$

We extract in a nonlinear way a sequence of functions (atoms) approximating  $f = K^\dagger * U^\dagger$ ,

$$\begin{aligned} f &\approx k_0 * u_0, \\ f &\approx (k_0 + k_1) * (u_0 + u_1), \\ &\dots \\ f &\approx (k_0 + k_1 + \dots + k_n) * (u_0 + u_1 + \dots + u_n) = K_n * U_n. \end{aligned}$$

This refined multiscale hierarchical blind deconvolution model will provide a better choice for the solution than the single step (variational) model, especially when reconstructing images with different scales, as each component  $(u_i, k_i)$  at a scale  $(\lambda_i, \mu_i)$  contains additional information that would have been ignored at the previous, coarser scales. As usual for ill-posed problems, we stop the iterations early, according to the discrepancy principle, in order to prevent meaningless computational steps.

We focus on Sobolev norms as regularizers for both kernel and image, and show that the iterates can be computed in a pointwise manner by means of the Fourier domain. When choosing the Fourier transforms of the kernels to be positive, we get the chance to break the unwanted symmetry which naturally occurs in such regularization frameworks. An interpretation of this choice in terms of positive definite functions is provided as well. Note that considering more modern penalties in our approach is beyond the scope of this study, since it would require accounting for a priori information and tedious computational methods specific to that setting.

Our work is structured as follows. Section 2 presents the convergence properties of the method, as well as the stopping rule. Section 3 is dedicated to the regularization with Sobolev norms, detailing the pointwise computation of the minimizers, while Section 4 illustrates the numerical experiments that fairly compare our procedure to a single-step variational method and to a non-blind deconvolution method.

## 2 Convergence properties and stopping rule

To the best of our knowledge, convergence results of the iterates  $U_n$  and  $K_n$  generated by the MHDM are not even known for simpler one-variable deblurring problems, see [37]. However, convergence of the residual  $f^\delta - K_n * U_n$  can be shown analogously to Theorems 2.1 and 2.3 in [21]. For completeness, we will provide a proof in the case of noisy data.

**Theorem 2.1.** *Let  $f = K^\dagger * U^\dagger$  be the blurry, but noise-free image, and let  $(U_n, K_n) = (\sum_{i=0}^n u_i, \sum_{i=0}^n k_i)$  with  $(u_i, k_i)$  attained from (6), (7) with  $f^\delta$  replaced by  $f$ . Assume that  $J_1$  and  $J_2$  are minimal at 0 and that there are  $C_1, C_2 \geq 1$  such that  $J_1(v_1 - v_2) \leq C_1(J_1(v_1) + J_1(v_2))$  and  $J_2(h_1 - h_2) \leq C_2(J_2(h_1) + J_2(h_2))$  for all  $v_1, v_2, h_1, h_2$ . Additionally, assume  $U^\dagger \in \text{dom } J_1$  and  $K^\dagger \in \text{dom } J_2$ . If  $\lambda_n$  and  $\mu_n$  are chosen such that  $\lambda_{n-1} \geq 2C\lambda_n$  and  $\mu_{n-1} \geq 2C\mu_n$  for all  $n \in \mathbb{N}$  with  $C = \max\{C_1, C_2\}$ , then  $\Phi(U_n, K_n, f)$  is decreasing in  $n$  and satisfies*

$$\Phi(U_n, K_n, f) \leq \frac{2C(\lambda_0 J_1(U^\dagger) + \mu_0 J_2(K^\dagger))}{n+1}. \quad (9)$$

It is well-known that iterative methods for ill-posed problems perturbed by noise have to be stopped early. We use the *discrepancy principle* as a stopping criterion, namely we terminate the iteration at index  $n^*(\delta)$  defined as

$$n^*(\delta) = \max\{n \in \mathbb{N} : \Phi(K_n, U_n, f^\delta) > \tau\delta^2\} + 1 \quad (10)$$

for some  $\tau > 1$ . The well-definedness of the stopping index  $n^*(\delta)$  is a consequence of the following Theorem, where for simplicity of notation the iterates obtained from the noisy observation  $f^\delta$  are still denoted by  $K_n$  and  $U_n$ .

**Theorem 2.2.** *Under the assumptions of Theorem 2.1, let  $U_n, K_n$  be obtained by (6) and (7). If  $\|n^\delta\|_{L^2} \leq \delta$  for some  $\delta > 0$  holds, then the residual  $\Phi(K_n, U_n, f^\delta)$  is decreasing in  $n$  and satisfies the estimate*

$$\Phi(K_n, U_n, f^\delta) \leq \frac{2C(\lambda_0 J_1(U^\dagger) + \mu_0 J_2(K^\dagger))}{n+1} + \delta^2. \quad (11)$$

If additionally  $(n^*(\delta))_{\delta>0}$  is unbounded as  $\delta \rightarrow 0$ , then  $(\Phi(K_{n^*(\delta)}, U_{n^*(\delta)}, f^\delta))_{\delta>0}$  converges to zero.

*Proof.* Let  $n_0 \in \mathbb{N}$ . We may assume  $\Phi(K_{n_0}, U_{n_0}, f^\delta) \geq \delta^2$ , as otherwise there is nothing to show. By the optimality of  $(u_n, k_n)$  in (7), it is

$$\Phi(K_n, U_n, f^\delta) + \lambda_n J_1(u_n) + \mu_n J_2(k_n) \leq \Phi(K_{n-1}, U_{n-1}, f^\delta) + \lambda_n J_1(0) + \mu_n J_2(0). \quad (12)$$

Together with by the minimality of  $J_1$  and  $J_2$  at 0, this implies that  $\Phi(K_n, U_n, f^\delta)$  is decreasing in  $n$ . On the other hand, comparing to  $(U^\dagger - U_{n-1}, K^\dagger - K_{n-1})$  yields

$$\begin{aligned} \Phi(U_n, K_n, f^\delta) + \lambda_n J_1(u_n) + \mu_n J_2(k_n) &\leq \Phi(U_{n-1} + (U^\dagger - U_{n-1}), K_{n-1} + (K^\dagger - K_{n-1}), f^\delta) \\ &\quad + \lambda_n J_1(U^\dagger - U_{n-1}) + \mu_n J_2(K^\dagger - K_{n-1}) \\ &\leq \delta^2 + \lambda_n J_1(U^\dagger - U_{n-1}) + \mu_n J_2(K^\dagger - K_{n-1}) \end{aligned} \quad (13)$$

Now, for any  $1 \leq j \leq n_0$  it is

$$\Phi(K_j, U_j, f^\delta) \geq \delta^2, \quad (14)$$

and we have

$$\begin{aligned} &\Phi(K_j, U_j, f^\delta) + \lambda_j J_1(U^\dagger - U_j) + \mu_j J_2(K^\dagger - K_j) \\ &= \Phi(K_j, U_j, f^\delta) + \lambda_j J_1(U^\dagger - u_j - U_{j-1}) + \mu_j J_2(K^\dagger - k_j - K_{j-1}) \\ &\leq \Phi(K_j, U_j, f^\delta) + C(\lambda_j J_1(U^\dagger - U_{j-1}) + J_1(u_j) + \mu_j J_2(K^\dagger - K_{j-1}) + J_2(k_j)) \\ &= \Phi(K_j, U_j, f^\delta) + \lambda_j J_1(u_j) + \mu_j J_2(k_j) \\ &\quad + (C-1)(\lambda_j J_1(u_j) + \mu_j J_2(k_j)) \\ &\quad + C(\lambda_j J_1(U^\dagger - U_{j-1}) + \lambda_j J_2(K^\dagger - K_{j-1})) \\ &\stackrel{(13)}{\leq} \delta^2 + (C-1)(\lambda_j J_1(u_j) + \mu_j J_2(k_j)) \\ &\quad + (C+1)(\lambda_j J_1(U^\dagger - U_{j-1}) + \mu_j J_2(K^\dagger - K_{j-1})) \\ &\stackrel{(13)}{\leq} \delta^2 + (C-1)(\delta^2 - \Phi(K_j, U_j, f) + \lambda_j J_1(U^\dagger - U_{j-1}) + \mu_j J_2(K^\dagger - K_{j-1})) \\ &\quad + (C+1)(\lambda_j J_1(U^\dagger - U_{j-1}) + \mu_j J_2(K^\dagger - K_{j-1})) \end{aligned}$$

$$\stackrel{(14)}{\leq} \delta^2 + 2C (\lambda_j J_1(U^\dagger - U_{j-1}) + \mu_j J_2(K^\dagger - K_{j-1})).$$

Therefore the choice  $\lambda_{j-1} \geq 2C\lambda_j$  and  $\mu_{j-1} \geq 2C\mu_j$  yields

$$\Phi(K_j, U_j, f^\delta) + \lambda_j J_1(U^\dagger - U_j) + \mu_j J_2(K^\dagger - K_j) \leq \delta^2 + \lambda_{j-1} J_1(U^\dagger - U_{j-1}) + \mu_{j-1} J_2(K^\dagger - K_{j-1}). \quad (15)$$

Using 0 instead of  $U_{j-1}$  and  $K_{j-1}$  in the previous calculations, one obtains for  $j = 0$  that

$$\Phi(K_0, U_0, f^\delta) + \lambda_0 J_1(U^\dagger - U_0) + \mu_0 J_2(K^\dagger - K_0) \leq \delta^2 + 2C(\lambda_0 J_1(U^\dagger) + \mu_0 J_2(K^\dagger)). \quad (16)$$

Using (15) repeatedly for  $j = 1, \dots, n_0$  and employing the non-negativity of  $J_1$  and  $J_2$ , it is

$$\begin{aligned} (n_0 + 1)\Phi(U_{n_0}, K_{n_0}, f) &\stackrel{(12)}{\leq} \sum_{j=0}^{n_0} \Phi(U_j, K_j, f) + (\lambda_{n_0} J_1(U^\dagger - U_{n_0}) + \mu_{n_0} J_2(K^\dagger - K_{n_0})) \\ &\stackrel{(15)}{\leq} \delta^2 + \sum_{j=0}^{n_0-1} \Phi(U_j, K_j, f) + (\lambda_{n_0-1} J_1(U^\dagger - U_{n_0-1}) + \mu_{n_0-1} J_2(K^\dagger - K_{n_0-1})) \\ &\leq \dots \leq (n_0)\delta^2 + (\lambda_0 J_1(U^\dagger - U_0) + \mu_0 J_2(K^\dagger - K_0)) \\ &\stackrel{(16)}{\leq} (n_0 + 1)\delta^2 + 2C (\lambda_0 J_1(U^\dagger) + \mu_0 J_2(K^\dagger)). \end{aligned}$$

Dividing by  $n_0 + 1$  proves (11).  $\square$

### 3 Sobolev norm regularizers

In order to illustrate our proposed method, we follow the work [6] and use Sobolev norms as regularizers for kernels and images. That is, we consider the case  $\Phi(K, U, f) = \|K * U - f\|_{L^2}^2 + \delta_{S_1}(U) + \delta_{S_2}(K)$ ,  $J_1 = \|\cdot\|_{H^r}^2$ , and  $J_2 = \|\cdot\|_{H^s}^2$  for  $r, s \geq 0$ . For defining the Bessel Potential norm for  $r \in \mathbb{R}$  we set  $\Delta(x) = 1 + |x|^2$ . Then

$$\|u\|_{H^r}^2 = \int_{\mathbb{R}^2} \Delta(x)^r |\hat{u}(x)|^2 dx \quad (17)$$

where  $\hat{u}$  is the Fourier transform of  $u$ . Note that the well-definedness of the MHDM with those regularizers follows analogously to [19, Theorem 3.6] for all sets of constraints that are closed under addition and satisfy  $S_1 \cap \text{dom } J_1 \neq \emptyset$  and  $S_2 \cap \text{dom } J_2 \neq \emptyset$ . However, we will start with analyzing the MHDM without any constraints (i.e.  $S_1 = S_2 = L^2(\mathbb{R}^2)$ ). Hence, we compute the first iterate  $(U_0, K_0)$  via

$$\min_{u, k \in L^2(\mathbb{R}^2)} \|k * u - f\|_{L^2}^2 + \lambda_0 \|u\|_{H^r}^2 + \mu_0 \|k\|_{H^s}^2. \quad (18)$$

The norm defined in (17) is a different, but equivalent norm than the one used in [6]. Nonetheless, the results of [6, Lemma 3.3] still hold: Denote the Fourier transform of  $f$  by  $\hat{f}$  and  $\bar{z}$  the complex conjugate of a complex number  $z$ . Then, the Fourier transforms  $(\hat{u}_0, \hat{k}_0)$  of all minimizers of (18) are pointwise given as

$$\hat{u}_0 = \text{sgn}(\bar{\psi} \hat{f}) \sqrt{\left[ \sqrt{\frac{\mu_0}{\lambda_0}} \Delta^{s-r} |\hat{f}| - \mu_0 \Delta^s \right]_+}, \quad (19)$$

$$\hat{k}_0 = \text{sgn}(\psi) \sqrt{\left[ \sqrt{\frac{\lambda_0}{\mu_0}} \Delta^{r-s} |\hat{f}| - \lambda_0 \Delta^r \right]_+}, \quad (20)$$

for arbitrary measurable functions  $\psi$  with  $\psi(x) \neq 0$  for all  $x$ . Here  $[w]_+ := \max\{w, 0\}$  and

$$\text{sgn}(z) = \begin{cases} \frac{z}{|z|}, & \text{if } z \neq 0, \\ 0, & \text{if } z = 0, \end{cases}$$

for  $z \in \mathbb{C}$ . Generally, applying the inverse Fourier transform to (19) and (20) gives *complex-valued* minimizers of (18). Thus, in order to obtain real-valued minimizers we need an appropriate choice for the function  $\psi$ . For this, recall the following result.

**Proposition 3.1.** *Let  $u \in L^2(\mathbb{R}^d, \mathbb{C})$  with Fourier transform  $\hat{u}$ . Then*

$$\text{leftmirgin} = 2em \quad \hat{u} \text{ is real-valued if and only if } u \text{ satisfies } u(x) = \overline{u(-x)} \text{ for all } x \in \mathbb{R}^d.$$

*leftmirgin* = 2em  $u$  is real-valued if and only if  $\hat{u}$  satisfies  $\hat{u}(x) = \overline{\hat{u}(-x)}$  for all  $x \in \mathbb{R}^d$ .

*Proof.* See [5, Chapter 1]. □

Since the image  $f$  is real-valued, we obtain  $\hat{f}(x) = \overline{\hat{f}(-x)}$  for all  $x \in \mathbb{R}^2$ . Moreover, due to the symmetry of  $\Delta(x)$ , we choose  $\psi$  such that  $\psi(x) = \overline{\psi(-x)}$  for all  $x \in \mathbb{R}^2$ , thereby ensuring that the inverse Fourier transforms of  $\hat{u}_0$  and  $\hat{k}_0$  are real-valued.

For our method, we choose  $\psi = 1$  and compute  $u_0, k_0$  by applying the inverse Fourier transform. With this choice, we can interpret  $\hat{u}_0$  as the pointwise square root of a shrinkage operator applied to  $\hat{f}$ . In particular, small frequencies in Fourier domain are eliminated, which removes noise. Furthermore, the choice  $\psi = 1$  means that the Fourier transform of  $k_0$  is non-negative almost everywhere. Let us also give an interpretation of this. First, recall the notion of positive semi-definite functions (see, e.g. [30, Section 4.4.3]).

**Definition 3.2.** A function  $\varphi : \mathbb{R}^d \rightarrow \mathbb{C}$  is positive semi-definite if

$$\sum_{l,m=1}^N \varphi(x_l - x_m) \xi_l \bar{\xi}_m \text{ is real-valued and satisfies } \sum_{l,m=1}^N \varphi(x_l - x_m) \xi_l \bar{\xi}_m \geq 0 \quad (21)$$

for all  $x_1, \dots, x_N \in \mathbb{R}^d$ ,  $\xi_1, \dots, \xi_N \in \mathbb{C}$  and any  $N \in \mathbb{N}$ .

**Lemma 3.3.** Let  $k : \mathbb{R}^d \rightarrow \mathbb{C}$  be a function such that its Fourier transform  $\hat{k}$  is non-negative almost everywhere. Then  $k$  is positive semi-definite.

*Proof.* It follows analogously to the proof of [30, Theorem 4.89]. □

This means, the kernel  $k_0$  obtained from choosing  $\psi = 1$  in (20) is positive semi-definite. In particular, it has the following properties, as one can see from (21) and Proposition 3.1.

**Corollary 3.4.** Let  $\varphi : \mathbb{R}^d \rightarrow \mathbb{C}$  be positive semi-definite. Then

*leftmirgin* = 2em  $\varphi(0)$  is real-valued and non-negative,

*leftmiirgin* = 2em  $|\varphi(x)| \leq \varphi(0)$  for all  $x \in \mathbb{R}^d$ ,

*leftmiirgiin* = 2em  $\varphi(-x) = \overline{\varphi(x)}$  for all  $x \in \mathbb{R}^d$ .

*Proof.* See Chapter 12, Lemma 3 in [11]. □

Thus,  $k_0$  attains a maximum at  $x = 0$ . Moreover, the solutions of (18) will be even functions with a peak at  $x = 0$ , so that they might be particularly useful to approximate conical combinations of centered Gaussians.

We therefore want to have the constraint that the images have the same Fourier phase as  $\hat{f}$  and the kernels have non-negative Fourier-transforms for all iterates of the MHDm. In the following we will show that the iterates of the MHDm with  $S_1 = S_2 = L^2(\mathbb{R}^2)$  can indeed be chosen to have this property. As a result, we obtain an explicit way to compute the iterates pointwise as certain minimizers of (7) without having to enforce the constraints that  $\text{sgn}(\hat{U}_n) = \text{sgn}(\hat{f})$  and that  $\hat{K}_n$  is non-negative.

## Computation of the increments

Let us start with deriving how to compute the increments  $(u_{n+1}, k_{n+1})$  for  $n \geq 0$ . Generally, we have to solve problems of the form

$$(u_{n+1}, k_{n+1}) \in \arg \min_{u, k \in L^2(\mathbb{R}^2)} \|(u + U_n) * (k + K_n) - f\|_{L^2}^2 + \lambda_{n+1} \|u\|_{H^r}^2 + \mu_{n+1} \|k\|_{H^s}^2. \quad (22)$$

Thus, in the Fourier space, this amounts to solving

$$(\hat{u}_{n+1}, \hat{k}_{n+1}) \in \arg \min_{\hat{u}, \hat{k} \in L^2(\mathbb{R}^2, \mathbb{C})} \left\{ \int_{\mathbb{R}^2} \left| (\hat{u}(x) + \hat{U}_n(x))(\hat{k}(x) + \hat{K}_n(x)) - \hat{f}(x) \right|^2 dx + \lambda_{n+1} \Delta(x)^r |\hat{u}(x)|^2 + \mu_{n+1} \Delta(x)^s |\hat{k}(x)|^2 \right\}. \quad (23)$$

As for computing minimizers in the initial step (18), we would like to solve (23) pointwise. Following the notation of [6], we fix  $x \in \mathbb{R}^2$  and set

$$a_{n+1} = \lambda_{n+1} \Delta^r(x), \quad b_{n+1} = \mu_{n+1} \Delta^s(x),$$

$$q_n = \hat{K}_n(x), \quad p_n = \hat{U}_n(x), \quad z = \hat{f}(x). \quad (24)$$

Hence, we are concerned with computing

$$(p_{n+1}^*, q_{n+1}^*) \in \arg \min_{p, q \in \mathbb{C}} f_n(p, q) := \arg \min_{p, q \in \mathbb{C}} |(p + p_n)(q + q_n) - z|^2 + a_{n+1} |p|^2 + b_{n+1} |q|^2, \quad (25)$$

where  $p_{n+1}^* = \hat{u}_{n+1}(x)$  and  $q_{n+1}^* = \hat{k}_{n+1}(x)$ . For the subsequent analysis of (25), we derive the first order optimality conditions with *complex* variables. To this end, we consider the problem as a minimization problem in  $\mathbb{R}^2$ . We start with the following observation. For any complex number  $w = \text{Re}(w) + i\text{Im}(w)$ , we write the canonical embedding into  $\mathbb{R}^2$  as  $\tilde{w} = (\text{Re}(w), \text{Im}(w))^T$ . Hence, for  $u, v, w \in \mathbb{C}$  it is

$$|vu - w|_2^2 = \left\| \begin{pmatrix} \tilde{v}_1 & -\tilde{v}_2 \\ \tilde{v}_2 & \tilde{v}_1 \end{pmatrix} \tilde{u} - \tilde{w} \right\|_2^2$$

Taking the gradient with respect to  $\tilde{u}$ , then gives

$$\nabla_{\tilde{u}} \left( \left\| \begin{pmatrix} \tilde{v}_1 & -\tilde{v}_2 \\ \tilde{v}_2 & \tilde{v}_1 \end{pmatrix} \tilde{u} - \tilde{w} \right\|_2^2 \right) = 2 \begin{pmatrix} \tilde{v}_1 & \tilde{v}_2 \\ -\tilde{v}_2 & \tilde{v}_1 \end{pmatrix} \left( \begin{pmatrix} \tilde{v}_1 & -\tilde{v}_2 \\ \tilde{v}_2 & \tilde{v}_1 \end{pmatrix} \tilde{u} - \tilde{w} \right) = 2\bar{v}(vu - w).$$

Therefore, the first order optimality conditions of (25) are given by

$$(\bar{q} + \bar{q}_n)((p + p_n)(q + q_n) - z) + a_{n+1}p = 0, \quad (26)$$

$$(\bar{p} + \bar{p}_n)((p + p_n)(q + q_n) - z) + b_{n+1}q = 0. \quad (27)$$

The following Theorem shows that it is possible to choose the increment  $q_n^*$  non-negative for all  $n \in \mathbb{N}$ , which therefore yields that the iterates  $q_n$  are non-negative, for all  $n \in \mathbb{N}$ .

**Theorem 3.5.** *There is a choice for  $(p_n^*, q_n^*)$  such that*

$$\text{leftmirgin} = 2em \quad q_n \in [0, \infty),$$

$$\text{leftmiirgiin} = 2em \quad \bar{z}p_n = z\bar{p}_n \in [0, \infty),$$

$$\text{leftmiirgiin} = 2em \quad \bar{z}p_n q_n \leq |z|^2$$

for all  $n \in \mathbb{N}_0$ . Here  $p_0^* = p_0$  and  $q_0^* = q_0$  are understood as the solution of (25) with  $p_{-1} = q_{-1} = 0$ .

*Proof.* If  $z = 0$ , then  $p_n = q_n = 0$  for all  $n \in \mathbb{N}$ , and the claim follows trivially. Hence, we assume  $z \neq 0$ . Since  $a_{n+1} > 0$  for all  $n \in \mathbb{N}_0$ , equation (26) is equivalent to

$$p + p_n = \frac{a_{n+1}p_n + z(\bar{q} + \bar{q}_n)}{|q + q_n|^2 + a_{n+1}}. \quad (28)$$

With this, we can prove the claims by induction.

**Base case:** Choose  $q_0^* \in [0, \infty)$  according to (19). Therefore, one has  $\bar{q}_0 = q_0 = q_0^*$  and, by (28), it follows that

$$\bar{z}p_0^* = \bar{z}p_0 = \frac{\bar{z}zq_0}{|q_0|^2 + a_1} = \frac{q_0 |z|^2}{|q_0|^2 + a_1} \geq 0,$$

and

$$\bar{z}p_0 q_0 = \frac{|q_0|^2 |z|^2}{|q_0|^2 + a_1} = \frac{|q_0|^2}{|q_0|^2 + a_1} |z|^2 \leq |z|^2.$$

Therefore, (i)–(iii) follow for the case  $n = 0$ .

**Induction step:** Assume (i)–(iii) hold for some  $n \in \mathbb{N}_0$ . In particular, this means  $\bar{q}_n = q_n$ , so that (28) becomes

$$p + p_n = \frac{a_{n+1}p_n + z(\bar{q} + q_n)}{|q + q_n|^2 + a_{n+1}}. \quad (29)$$

Hence, we can restrict the minimization of  $f_n$  to minimizing over the set of all  $(p, q)$ , for which  $p$  satisfies (29). We thus need to minimize the functional

$$\tilde{f}_n(q) := \left| \frac{a_{n+1}p_n(q + q_n) + z|q + q_n|^2}{|q + q_n|^2 + a_{n+1}} - z \right|^2 + a_{n+1} \left| \frac{a_{n+1}p_n + z(\bar{q} + q_n)}{|q + q_n|^2 + a_{n+1}} - p_n \right|^2 + b_{n+1} |q|^2$$

$$\begin{aligned}
&= \left| \frac{a_{n+1}p_n(q+q_n) - a_{n+1}z}{|q+q_n|^2 + a_{n+1}} \right|^2 + a_{n+1} \left| \frac{z(\bar{q}+q_n) - p_n|q+q_n|^2}{|q+q_n|^2 + a_{n+1}} \right|^2 + b_{n+1}|q|^2 \\
&= \frac{a_{n+1}^2}{(|q+q_n|^2 + a_{n+1})^2} |p_n(q+q_n) - z|^2 + \frac{a_{n+1}|q+q_n|^2}{(|q+q_n|^2 + a_{n+1})^2} |z - p_n(q+q_n)|^2 + b_{n+1}|q|^2 \\
&= \left( \frac{a_{n+1}^2}{(|q+q_n|^2 + a_{n+1})^2} + \frac{a_{n+1}|q+q_n|^2}{(|q+q_n|^2 + a_{n+1})^2} \right) |p_n(q+q_n) - z|^2 + b_{n+1}|q|^2 \\
&= \frac{a_{n+1}}{|q+q_n|^2 + a_{n+1}} |p_n(q+q_n) - z|^2 + b_{n+1}|q|^2.
\end{aligned}$$

leftmirgin = 2em In order to show that  $q_{n+1} \geq 0$ , we only need to show that we can choose  $q_{n+1}^* \geq 0$ . First, observe that  $\tilde{f}_n$  must attain a minimum by coercivity and continuity. Therefore, let  $\tilde{q}$  be a minimizer of  $\tilde{f}_n$ . Hence, it suffices to prove  $\tilde{f}_n(\tilde{q}) \geq \tilde{f}_n(|\tilde{q}|)$ . Let now  $r \geq 0$ . We show that on the set  $\{q \in \mathbb{C} : |q| = r\}$ , the choice  $q = r$  minimizes  $\tilde{f}_n$ . Indeed, for  $q$  with  $|q| = r$ , it holds

$$\begin{aligned}
\tilde{f}_n(q) &= \frac{a_{n+1}}{|q+q_n|^2 + a_{n+1}} |p_n(q+q_n) - z|^2 + b_{n+1}|q|^2 \\
&= \frac{a_{n+1}}{r^2 + |q_n|^2 + 2q_n \operatorname{Re}(q) + a_{n+1}} |p_n(q+q_n) - z|^2 + b_{n+1}r^2 \\
&\geq \frac{a_{n+1}}{r^2 + |q_n|^2 + 2q_nr + a_{n+1}} |p_n(q+q_n) - z|^2 + b_{n+1}r^2 \\
&= \frac{a_{n+1}}{|r+q_n|^2 + a_{n+1}} |p_n(q+q_n) - z|^2 + b_{n+1}r^2 \\
&= \frac{a_{n+1}}{(|r+q_n|^2 + a_{n+1})|z|^2} \left| \bar{z}p_n(q+q_n) - |z|^2 \right|^2 + b_{n+1}r^2 \\
&= \frac{a_{n+1}}{(|r+q_n|^2 + a_{n+1})|z|^2} \left( (\bar{z}p_n)^2|q|^2 + (\bar{z}p_nq_n - |z|^2)^2 + 2(\bar{z}p_n)(\bar{z}p_nq_n - |z|^2)\operatorname{Re}(q) \right) + b_{n+1}r^2 \\
&= \frac{a_{n+1}}{(|r+q_n|^2 + a_{n+1})|z|^2} \left( (\bar{z}p_n)^2r^2 + (\bar{z}p_nq_n - |z|^2)^2 + 2(\bar{z}p_n)(\bar{z}p_nq_n - |z|^2)\operatorname{Re}(q) \right) + b_{n+1}r^2 \\
&\geq \frac{a_{n+1}}{(|r+q_n|^2 + a_{n+1})|z|^2} \left( (\bar{z}p_n)^2r^2 + (\bar{z}p_nq_n - |z|^2)^2 + 2(\bar{z}p_n)(\bar{z}p_nq_n - |z|^2)r \right) + b_{n+1}r^2 \\
&= \frac{a_{n+1}}{(|r+q_n|^2 + a_{n+1})|z|^2} \left| \bar{z}p_n(r+q_n) - |z|^2 \right|^2 + b_{n+1}r^2 \\
&= \tilde{f}_n(r),
\end{aligned}$$

where the last inequality follows from  $\bar{z}p_n \geq 0$  and  $\bar{z}p_nq_n \leq |z|^2$ . Thus, for any  $r \geq 0$  the minimum of  $\tilde{f}_n$  on the circle of radius  $r$  is attained for  $q = r$ . In particular, we obtain  $\tilde{f}_n(\tilde{q}) \geq \tilde{f}_n(|\tilde{q}|)$ .

leftmiirgiin = 2em From the previous part, we know that there is a pair  $(p_{n+1}^*, q_{n+1}^*)$  minimizing  $f_n$  such that  $q_{n+1}^* \geq 0$ . By definition, it is  $p_{n+1} = p_{n+1}^* + p_n$ , so we can multiply (29) with  $\bar{z}$  to obtain

$$\bar{z}p_{n+1} = \bar{z} \frac{a_{n+1}p_n + z(q_n^* + q_n)}{|q_n^* + q_n|^2 + a_{n+1}} = \frac{a_{n+1}\bar{z}p_n + |z|^2 q_{n+1}}{|q_{n+1}|^2 + a_{n+1}} \geq 0.$$

leftmiirgiin = 2em If  $p_{n+1} = 0$ , the claim follows trivially. Thus, we assume  $p_{n+1} \neq 0$  and find from (27) that

$$\bar{p}_{n+1}(q_{n+1}p_{n+1} - z) + b_{n+1}q_{n+1}^* = 0.$$

Multiplying with  $\bar{z}$  and rearranging implies

$$\bar{z}p_{n+1}q_{n+1} = -b_{n+1}q_{n+1}^* \frac{\bar{z}}{\bar{p}_{n+1}} + |z|^2.$$

Denote  $\varphi_z = \arg z$  and  $\varphi_{p_{n+1}} = \arg p_{n+1}$ . It is

$$\frac{\bar{z}}{\bar{p}_{n+1}} = |z| |p_{n+1}|^{-1} e^{-i\varphi_z} (e^{-i\varphi_{p_{n+1}}})^{-1} = \frac{|z|}{|p_{n+1}|} e^{i(\varphi_{p_{n+1}} - \varphi_z)} \geq 0,$$

since  $\varphi_{p_{n+1}} - \varphi_z = \arg(\bar{z}p_{n+1})$ . Therefore,  $-b_{n+1}q_{n+1}^* \frac{\bar{z}}{\bar{p}_{n+1}} \leq 0$ , which yields  $\bar{z}p_{n+1}q_{n+1} \leq |z|^2$ .

□

Note that we can use  $q_{n+1}^*$  instead of  $q$  in (28) to compute  $p_{n+1}^*$ . Consequently  $\hat{U}_{n+1}$  is obtained pointwise via

$$\hat{U}_{n+1} = \frac{(\lambda_{n+1}\Delta^s)\hat{U}_n + \hat{f}\hat{K}_{n+1}}{\left|\hat{K}_{n+1}\right|^2 + \lambda_{n+1}\Delta^s}. \quad (30)$$

However, this does not guarantee that applying the inverse Fourier transform to  $\hat{U}_{n+1}$  and  $\hat{K}_{n+1}$  yields real-valued solutions of (22). In order to find such solutions we make use of the following observation.

**Lemma 3.6.** *Assume that  $U_n$  and  $K_n$  are real valued and let  $x \in \mathbb{R}^2$ . If  $(u^*, k^*)$  is a solution to*

$$(u^*, k^*) \in \arg \min_{u, k \in L^2(\mathbb{R}^2, \mathbb{C})} \left\{ \left| \hat{f}(x) - (u + \hat{U}_n(x))(k + \hat{K}_n(x)) \right|^2 + \lambda_{n+1}\Delta(x)^r |u|^2 + \mu_{n+1}\Delta(x)^s |k|^2 \right\},$$

then  $(\bar{u}^*, \bar{k}^*)$  is a solution of

$$(u^*, k^*) \in \arg \min_{u, k \in L^2(\mathbb{R}^2, \mathbb{C})} \left\{ \left| \hat{f}(-x) - (u + \hat{U}_n(-x))(k + \hat{K}_n(-x)) \right|^2 + \lambda_{n+1}\Delta(-x)^r |u|^2 + \mu_{n+1}\Delta(-x)^s |k|^2 \right\}.$$

*Proof.* Note that  $\hat{f}(x) = \overline{\hat{f}(-x)}$ ,  $\hat{U}_n(x) = \overline{\hat{U}_n(-x)}$ , and  $\hat{K}_n(x) = \overline{\hat{K}_n(-x)}$  by Proposition 3.1. Furthermore, we have  $\Delta(x) = \Delta(-x)$ . Let

$$h(u, k) := \left| \hat{f}(x) - (u + \hat{U}_n(x))(k + \hat{K}_n(x)) \right|^2 + \lambda_{n+1}\Delta(x)^r |u|^2 + \mu_{n+1}\Delta(x)^s |k|^2,$$

and

$$\tilde{h}(u, k) := \left| \hat{f}(-x) - (u + \hat{U}_n(-x))(k + \hat{K}_n(-x)) \right|^2 + \lambda_{n+1}\Delta(-x)^r |u|^2 + \mu_{n+1}\Delta(-x)^s |k|^2.$$

Since it holds that

$$\begin{aligned} \tilde{h}(\bar{u}, \bar{v}) &= \left| \hat{f}(-x) - (\bar{u} + \hat{U}_n(-x))(\bar{k} + \hat{K}_n(-x)) \right|^2 + \lambda_{n+1}\Delta(-x)^r |\bar{u}|^2 + \mu_{n+1}\Delta(-x)^s |\bar{k}|^2 \\ &= \left| \overline{\hat{f}(x)} - (\bar{u} + \overline{\hat{U}_n(x)})(\bar{k} + \overline{\hat{K}_n(x)}) \right|^2 + \lambda_{n+1}\Delta(x)^r |\bar{u}|^2 + \mu_{n+1}\Delta(x)^s |\bar{k}|^2 \\ &= \left| \hat{f}(x) - (u + \hat{U}_n(x))(k + \hat{K}_n(x)) \right|^2 + \lambda_{n+1}\Delta(x)^r |u|^2 + \mu_{n+1}\Delta(x)^s |k|^2 = h(u, k), \end{aligned}$$

the claim follows. □

Combining Theorem 3.5 and Lemma 3.6 shows that we can choose the sequence  $(U_n, K_n)_{n \in \mathbb{N}_0}$  such that  $U_n$  and  $K_n$  are real valued, and  $\hat{K}_n$  is non-negative for every  $n \in \mathbb{N}$ . We summarize this in the following Lemma.

**Lemma 3.7.** *There are sequences  $(U_n, K_n)_{n \in \mathbb{N}_0}$  of real-valued functions with*

$$(U_0, K_0) \in \arg \min_{u, k \in L^2(\mathbb{R}^2)} \left\{ \|f - k * u\|_{L^2}^2 + \lambda_0 \|u\|_{H^r}^2 + \mu_0 \|k\|_{H^s}^2 \right\}$$

and

$$(U_{n+1} - U_n, K_{n+1} - K_n) \in \arg \min_{u, k \in L^2(\mathbb{R}^2)} \left\{ \|f - (k + K_n) * (u + U_n)\|_{L^2}^2 + \lambda_{n+1} \|u\|_{H^r}^2 + \mu_{n+1} \|k\|_{H^s}^2 \right\}$$

for  $n \in \mathbb{N}_0$ , such that  $\hat{K}_n$  is real-valued and non-negative. Moreover  $(U_n, K_n)$  can iteratively be computed as follows:

*leftmirgin = 2em*  $U_0$  and  $K_0$  are the inverse Fourier transforms of  $\hat{U}_0$  and  $\hat{K}_0$  in (19) and (20), respectively, with  $\Psi = 1$ .

*leftmirgin = 2em* For  $n \in \mathbb{N}_0$ ,  $U_{n+1}$  and  $K_{n+1}$  are the inverse Fourier transforms of  $\hat{U}_{n+1} = \hat{U}_n + \hat{u}_{n+1}$  and  $\hat{K}_{n+1} = \hat{K}_n + \hat{k}_{n+1}$ , where  $\hat{u}_{n+1}$ ,  $\hat{k}_{n+1}$  solve

$$(\hat{u}_{n+1}, \hat{k}_{n+1}) \in \arg \min_{\hat{u}, \hat{k} \in L^2(\mathbb{R}^2, \mathbb{C})} \left\{ \left\| \hat{f} - (\hat{u} + \hat{U}_n)(\hat{k} + \hat{K}_n) \right\|_{L^2}^2 + \lambda_{n+1} \|\Delta^r \hat{u}\|_{L^2}^2 + \mu_{n+1} \|\Delta^s \hat{k}\|_{L^2}^2 \right\}$$

and satisfy  $\hat{k}_{n+1}(x) \in [0, \infty)$ ,  $\hat{k}_{n+1}(x) = \hat{k}_{n+1}(-x)$ ,  $\hat{u}_{n+1}(x) = \overline{\hat{u}_{n+1}(-x)}$  for all  $x \in \mathbb{R}^2$ , as well as  $\text{sgn}(\hat{u}_{n+1}) = \text{sgn}(\hat{f})$ .

*Proof.* From Lemma 3.6, we know that it suffices to find sequences  $(\hat{U}_n, \hat{K}_n)_{n \in \mathbb{N}}$  of pointwise minimizers of the integrand in (22) on the half-plane  $\in [0, \infty) \times \mathbb{R}$ . The existence of such  $\hat{K}_n$  follows from Theorem 3.5. In particular, we have  $\hat{K}_n(x) \in [0, \infty)$  so that by induction over (30) we obtain  $\hat{U}_n$  with  $\text{sgn}(\hat{U}_n(x)) = \text{sgn}(\hat{f}(x))$ . Now, extend  $\hat{U}_n$  and  $\hat{K}_n$  by setting  $\hat{K}_n(x) := \hat{K}_n(-x)$  and  $\hat{U}_n(x) := \hat{U}_n(-x)$  on  $(-\infty, 0] \times \mathbb{R}$ . According to Lemma 3.6 these extended functions are minimizers of (23). The realness of the inverse Fourier transforms is a consequence of Proposition 3.1 and the fact that  $f$  is real-valued.  $\square$

We can now construct a method to directly solve (25). Following the proof of Lemma 3.7, it suffices to solve (25) pointwise for  $x \in [0, \infty) \times \mathbb{R}$ . For better readability, we again use the notation (24). First, we plug (29) in (27) to obtain

$$\left| \frac{a_{n+1}p_n + z(\bar{q} + q_n)}{|q + q_n|^2 + a_{n+1}} \right|^2 (q + q_n) - z \frac{a_{n+1}\bar{p}_n + \bar{z}(q + q_n)}{|q + q_n|^2 + a_{n+1}} + b_{n+1}q = 0.$$

Multiplying with  $(|q + q_n|^2 + a_{n+1})^2$ , we get

$$\begin{aligned} & |a_{n+1}\bar{p}_n + \bar{z}(q + q_n)|^2 (q + q_n) \\ & - (a_{n+1}z\bar{p}_n + |z|^2(q + q_n))(|q + q_n|^2 + a_{n+1}) \\ & + b_{n+1}q(|q + q_n|^2 + a_{n+1})^2 = 0. \end{aligned} \quad (31)$$

Since we are interested in finding a real solution of this equation, we can assume  $q \in \mathbb{R}$  and expand to

$$\begin{aligned} & b_{n+1}(q + q_n)^5 - b_{n+1}q_n(q + q_n)^4 + 2a_nb_{n+1}(q + q_n)^3 \\ & + [2a_{n+1}\text{Re}(\bar{p}_nz) - a_nz\bar{p}_n - 2a_nb_{n+1}q_n](q + q_n)^2 \\ & + [a_{n+1}^2|p_n|^2 - a_{n+1}|z|^2 + a_{n+1}^2b_{n+1}](q + q_n) - a_{n+1}^2(z\bar{p}_n + b_{n+1}q_n) = 0. \end{aligned} \quad (32)$$

Since both  $q_n$  and  $z\bar{p}_n$  are real numbers, this is a polynomial of degree 5 with only real coefficients. We can thus choose  $q_{n+1}^*$  to be the real root of (32), for which  $f_n$  as in (25) attains the smallest value. Then  $p_{n+1}^*$  is determined by (28). We have therefore computed  $\hat{u}_{n+1}$  and  $\hat{k}_{n+1}$  on  $[0, \infty) \times \mathbb{R}$ . Extending with complex conjugation to  $\mathbb{R}^2$  and taking the inverse Fourier transform, then gives real-valued solutions of (22), such that the  $\hat{k}_{n+1}$  is real-valued and non-negative. Thus, by choosing the those minimizers for which the Fourier transform of the kernel is real and non-negative in the MHDM iteration, we implicitly incorporate the constraint  $\hat{K}_n(x) \geq 0$  for all  $x$ . Therefore, all approximations of the kernel will be positive semi-definite enforcing properties (i)–(iii) in Corollary 3.4, that acts as a way to break the symmetry of problem (18).

**Remark.** If more information on the phase of the true kernel is available, one might want to choose  $\psi$  in (19) and (20) to be a different complex-valued function instead of a non-negative one. In this case, the sequence  $(\hat{u}_n, \hat{k}_n)_{n \in \mathbb{N}}$  generated by (23) can be chosen such that  $\text{sgn} \hat{k}_n = \text{sgn} \psi$  for all  $n \in \mathbb{N}$ . To see this, notice that substituting  $\text{sgn}(\psi)\hat{k}$ ,  $\text{sgn}(\psi)\hat{K}_n$ ,  $\text{sgn}(\bar{\psi}\hat{f})\hat{u}$  and  $\text{sgn}(\bar{\psi}\hat{f})\hat{U}_n$  for  $\hat{k}$ ,  $\hat{K}_n$ ,  $\hat{u}$  and  $\hat{U}_n$ , respectively, in (23), does not change the value of the objective function. Thus, we can use the iterates obtained with the constraint  $\hat{k} \geq 0$  to compute the iterates of a MHDM with the constraint  $\text{sgn}(\hat{k}) = \text{sgn}(\psi)$ .

In order to further ensure that the iterates are reasonable approximations of the true image and kernel, we additionally assume  $f \in L^1$  and impose constraints on their means:

$$\int_{\mathbb{R}^2} K_n = 1, \quad \int_{\mathbb{R}^2} U_n = \int_{\mathbb{R}^2} f \quad (33)$$

for all  $n \in \mathbb{N}$ . Those constraints are fairly standard and can for instance be found in [8, 17]. In summary, this means we are considering the constraint sets:

$$S_1 = \left\{ u : \mathbb{R}^2 \rightarrow \mathbb{R} : \int_{\mathbb{R}^2} u = \int_{\mathbb{R}^2} f \right\}, \quad S_2 = \left\{ k : \mathbb{R}^2 \rightarrow \mathbb{R} : \int_{\mathbb{R}^2} k = 1, \hat{k} \geq 0 \right\}.$$

It is not clear if these constraints can be translated into Fourier space such that the iterates of the MHDM can still be computed in a pointwise manner. Since for any function  $u \in L^1(\mathbb{R}^2)$  it is known that  $\hat{u}$  is uniformly continuous [4, p.1], it must be  $\int_{\mathbb{R}^2} u = \hat{u}(0)$ . However, simply enforcing the constraint  $\hat{U}_n(0) = \int_{\mathbb{R}^2} f$  in (23) does not affect  $\int_{\mathbb{R}^2} U_n$  as the resulting minimizer in Fourier space would only differ from the unconstrained one on a set of measure 0 and  $\hat{U}_n$  is an element of  $H^r(\mathbb{R}^n)$  and not necessarily of  $L^1(\mathbb{R}^n)$ . Note that this problem does not occur in the discretized setting we use for the numerical experiments, as will be outlined later.

**Remark.** Instead of employing a Bessel Potential norm as a penalty term for the image, it would be a natural idea to use a functional that favors expected structures. For instance, one could use the total variation to promote cartoon-like images. However, numerical experiments suggest that the iterates of such blind-deconvolution MHDMM seem to approximate the trivial solution  $u = f$  and  $k = \delta$ , where  $\delta$  denotes the Dirac delta distribution. This could possibly be overcome by a specific choice for the sequences  $(\lambda_n)_{n \in \mathbb{N}}$  and  $(\mu_n)_{n \in \mathbb{N}}$ , but would first require a deeper analysis of convergence behavior of the blind MHDMM in this scenario, which is not within the scope of this work.

## 4 Numerical Experiments<sup>1</sup>

The goal of our numerical experiments is to illustrate the behavior and robustness of the blind deconvolution MHDMM. To this end, we compare the reconstructed image and kernel from the proposed method to those obtained from using a non-blind MHDMM or a single step variational regularization, as in (18). To achieve a fair comparison, we use the same regularizers for all methods under investigation. By using squared Bessel Potential norms, we obtain reasonable reconstructions that might not necessarily outperform methods with more problem specific regularizers. However, we think that comparing our approach to such methods should be done with a version of the MHDMM that also uses more sophisticated regularizers, that is beyond the scope of this work. We want to stress that the advantage of our method is the interpretability of the scale decomposition and the potential to adapt it to a multitude of regularizers that possibly could vary along the iterations rather than significantly better reconstructions than those of a single-step variational approach with optimal regularization parameters.

### 4.1 Discretization and Implementation

Recall that  $J_1 = \|\cdot\|_{H^r}^2$  and  $J_2 = \|\cdot\|_{H^s}^2$  for  $r, s \geq 0$ . We discretize an image  $u$  supported on a rectangular domain  $(a, b) \times (c, d)$  as a matrix, i.e.,  $u \in \mathbb{R}^{m \times n}$ . Following the derivation in Section 7.1.2 of [19], we define the weight matrix for the Sobolev norm in Fourier space by the matrix  $\Delta \in \mathbb{R}^{m \times n}$  with entries

$$\Delta_{i,j} = 1 + 2m^2 \left(1 - \cos\left(\frac{2\pi i}{m}\right)\right) + 2n^2 \left(1 - \cos\left(\frac{2\pi j}{n}\right)\right).$$

Hence, a discretization of the Sobolev norm is given by

$$\|u\|_{H^r}^2 = \sum_{i=1}^m \sum_{j=1}^n \Delta_{i,j}^r |\hat{u}_{i,j}|^2,$$

where  $\hat{u}$  denotes the discrete 2D Fourier transform. Therefore, the  $n$ -th step of the MHDMM is given by the pointwise update rule

$$(\hat{k}_{i,j}^{(n)}, \hat{u}_{i,j}^{(n)}) \in \arg \min_{\hat{k}, \hat{u} \in \mathbb{C}} \left\{ \left( (\hat{k} + \hat{k}_{i,j}^{(n-1)}) (\hat{u} + \hat{u}_{i,j}^{(n-1)}) - \hat{f}_{i,j} \right)^2 + \lambda_n \Delta_{i,j}^r |\hat{u}|^2 + \mu_n \Delta_{i,j}^s |\hat{k}|^2 \right\}, \quad (34)$$

with  $\hat{k}_{i,j}^{-1} = u_{i,j}^{-1} = 0$ . Thus for  $n = 0$ , we can solve (34) by

$$\begin{aligned} \hat{u}_{i,j}^{(0)} &= \operatorname{sgn}(\hat{f}_{i,j}) \sqrt{\left[ \sqrt{\frac{\mu_0}{\lambda_0} \Delta_{i,j}^{s-r}} |\hat{f}_{i,j}| - \mu_0 \Delta_{i,j}^s \right]_+} \\ \hat{k}_{i,j}^{(0)} &= \sqrt{\left[ \sqrt{\frac{\lambda_0}{\mu_0} \Delta_{i,j}^{r-s}} |\hat{f}_{i,j}| - \lambda_0 \Delta_{i,j}^r \right]_+}. \end{aligned}$$

For  $n \geq 1$ , we make the same substitutions as in (24):

$$\begin{aligned} a_n &= \lambda_n \Delta_{i,j}^r, \quad b_n = \mu_n \Delta_{i,j}^s, \\ q_n &= \hat{k}_{i,j}^{(n-1)}, \quad p_n = \hat{u}_{i,j}^{(n-1)}, \quad z = \hat{f}_{i,j}, \end{aligned}$$

To find critical pairs  $(\hat{k}_{i,j}, \hat{u}_{i,j})$ , we compute the positive roots of (32) that yield candidates for  $\hat{k}_{i,j}$  and use (29) to obtain the corresponding candidates for  $\hat{u}_{i,j}$ . The minimizing pair can then be found by choosing the critical pair, which gives the smallest value for the objective function in (34) and enforce the anti-symmetry condition as described in the proof of Lemma 3.7. In order to obtain meaningful reconstructions  $u^{(n)}, k^{(n)}$ ,

<sup>1</sup>The program code is available as ancillary file from the arXiv page of this paper.

Figure 1: From left to right: true test image  $U^\dagger$ , observation obtained with single Gaussian blur and noise  $f_1^\delta$  and observation obtained with mixture of Gaussians and noise  $f_2^\delta$ .

Figure 2: Left: single Gaussian kernel used to obtain  $f_1^\delta$ , Right: Convex combination of multiple Gaussian kernels used to obtain  $f_2^\delta$ .

we employ the additional constraint (33) that the mean of the kernel is 1 and the mean of the reconstructed image matches the mean of the observation. In the discretization that means

$$\sum_{i=1}^m \sum_{j=1}^n k_{i,j}^{(n)} = 1, \quad \sum_{i=1}^m \sum_{j=1}^n u_{i,j}^{(n)} = \sum_{i=1}^m \sum_{j=1}^n f_{i,j}^{(n)}.$$

Since we are using discrete Fourier transforms, these constraints are equivalent to  $\hat{k}_{i,1} = 1$  and  $\hat{u}_{1,1} = \sum_{i=1}^m \sum_{j=1}^n f_{i,j}^{(n)}$ . Thus, we implement them by making the updates

$$\hat{k}_{1,1}^{(n)} = \begin{cases} 1 & \text{if } n = 0, \\ 0 & \text{if } n \geq 1. \end{cases} \quad \text{and} \quad \hat{u}_{1,1}^{(n)} = \begin{cases} \hat{f}_{1,1} & \text{if } n = 0, \\ 0 & \text{if } n \geq 1. \end{cases}$$

instead of the previous procedure for the first entries of the matrices.

## 4.2 Behavior of the blind-deconvolution MHDM

For illustrating the behavior of the proposed method, we consider the image *Barbara* (denoted by  $U^\dagger$ ), which has been blurred by convolution with two different kernels. For the first blurring we choose a Gaussian kernel  $K_1^\dagger$  of mean  $\mu = 0$  and variance  $\sigma = 8$ . In the second kernel  $K_2^\dagger$ , we use a convex combination of several Gaussians. In both cases, the blurred image was additionally corrupted with additive Gaussian noise (mean  $\mu = 0$ , variance  $\sigma = 4 \times 10^{-4}$ ). That is, we deal with observations  $f_1^\delta, f_2^\delta$  obtained via  $f_i^\delta = U_{\text{true}} * K_i + n^\delta$  for  $i = 1, 2$ . The true image, blurred images and noise corrupted blurred images can be found in Figure 1, the corresponding kernels are shown in Figure 2.

Curiously, the results of all our experiments (including the more extensive experiments later) improve if  $s$  is chosen smaller than  $r$ . This means, we penalize the image with a more smoothness promoting regularizer than the kernel. Furthermore, we observe that as long as the ratio  $\frac{\lambda_0}{\mu_0}$  is constant, the actual choice of the initial parameters  $\lambda_0, \mu_0$  does not significantly influence the quality of the final iterates but only the number

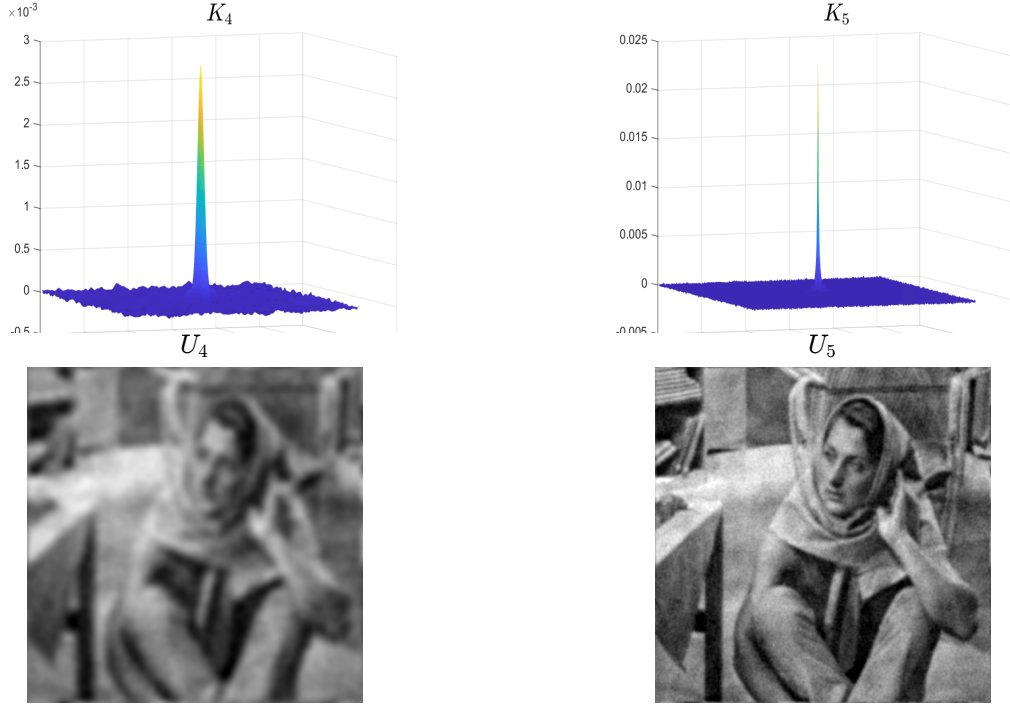

Figure 3: Left: reconstructed kernel and image at stopping index for data  $f_1^\delta$ . Right: reconstructed kernel and image at stopping index for data  $f_2^\delta$ .

Figure 4: Left: Residual of the blind MHDM and noise level for  $f_1^\delta$ , Right: Residual of the blind MHDM and noise level for  $f_2^\delta$ .

of iterations needed until the discrepancy principle is satisfied.

For our experiments we choose  $r = 1$  and  $s = 0.1$ , and run the MHDM with initial parameters  $\lambda_0 = 1.4 \times 10^{-4}$ ,  $\mu_0 = 6.3 \times 10^5$ . In accordance with Theorem 2.2, we choose the parameters at the  $n$ -th step as  $\lambda_n = 4^{-n}\lambda_0$  and  $\mu_n = 4^{-n}\mu_0$ . Since in this experiment we artificially added noise and hence know the exact noise level, the iteration is stopped according to the discrepancy principle (10) with  $\tau = \sqrt{1.001}$ .

The reconstructed kernels and images are illustrated in Figure 3. Figure 4 shows the decay of the residual for both experiments. In both figures, one can clearly see the monotone decrease of the residual, confirming the theoretical results from Theorem 2.1. Figure 5 shows the different scales  $u_n$  that are obtained with the MHDM employed for the observation  $f_2^\delta$ . One can see that each step adds another layer of details to the reconstruction. The corresponding scales  $k_n$  and iterates  $K_n = \sum_{i=0}^n k_i$  for the reconstructed kernel can be seen in Figures 6 and 7. It appears that the role of the scales is to adapt the reconstructed kernel in a twofold way. On the one side, the height of the peak seems to increase along the iterations, while its radius decreases. On the other side, the off-peak oscillations appear to be flattened. Notably, the early coarse scales seem to recover the support of the bump, and the fine scales mostly shape the height of it. In the experiment with data  $f_1^\delta$ , the scale decomposition for the reconstructed image and kernel look similar.

Moreover, the experiments suggest that a suboptimal choice for the initial ratio leads to a worse kernel reconstruction while, upon an affine rescaling of the grayscale values, the reconstructed images are visually still good. This is illustrated in Figure 8, where the reconstructed kernels and images (with the pixel values

Figure 5: Scale decomposition  $u_n$  obtained from  $f_2^\delta$ .

rescaled) for different initial parameters  $\lambda_0$  and  $\mu_0$  are shown. We observe that visually all images are indistinguishable and approximate the true image well. Similarly, the corresponding kernels are structurally similar to the real one, but their numerical values are very disproportional.

### 4.3 Experiment 1: Comparison of blind MHDM vs. non-blind MHDM

We compare the proposed blind MHDM to a non-blind version of the MHDM (see for instance [37, 26]) that uses the penalty term  $J = \|\cdot\|_{H^r}^2$  for the image. Instead of including the reconstruction of the blurring kernel in the method, we simply make a guess in the non-blind MHDM and stop the iteration once the discrepancy principle is satisfied. The non-blind MHDM therefore only requires the choice of one initial parameter  $\lambda_0$ , which we choose to be the same as for the blind deconvolution MHDM and also decrease according to the rule  $\lambda_n = 4^{-n}\lambda_0$ . To compare the two methods, we test the non-blind MHDM for 1000 centered Gaussian kernels with variances ranging between 1 and 12 as guessed kernels.

In Figures 9 and 10, we compare the performance of the blind MHDM with the non-blind MHDM algorithm in terms of the error measures PSNR, SSIM (Figure 9), and the  $L^2$ -error of the kernel (Figure 10). We consider either the data  $f_1^\delta$  (figures on the left-hand side) or  $f_2^\delta$  (figures on the right-hand side). In each of the plots, the values on the  $x$ -axis correspond to the guessed variance  $\sigma$  of the Gaussian kernel used for the non-blind MHDM. The full line corresponds to the values of the resulting respective error measures, whereas the constant dashed line represents the value of the blind MHDM. Clearly, the quality of the non-blind algorithms depends on the correctness of the choice of  $\sigma$ . For the observation  $f_1^\delta$ , which corresponds to blurring with a single Gaussian kernel, the non-blind MHDM expectedly outperforms the blind MHDM only for kernel guesses that are similar to the true kernel. We observe similar behavior for the case  $f_2^\delta$  with multiple Gaussian kernels used in the blurring. However, let us point out that, especially for the error measures PSNR and SSIM, the non-blind method has only a rather modest advantage and only in the case when the “guessed”  $\sigma$  is close to the true one, while in case of a wrong guess, the non-blind method can go wrong quite dramatically as can be seen from the experiments with observation  $f_2^\delta$  (the bottom line in Figure 9). To further test this information, we repeat the experiment for 16 different test images, where each of those is corrupted by 3 different blurring kernels: Kernel 1 is a single centered Gaussian kernel with variance 8 representing a strong blur, Kernel 2 is the convex combination of 4 different Gaussian kernels with variances ranging from 1 to 5 used in the previous experiments, while Kernel 3 is a centered Gaussian kernel with variance 2 and represents a mild blur. Additionally, to all blurred images we add Gaussian noise with respective variances 0.0004, 0.00004, 0.003. Thus we consider a total of 144 different test images. We then compute approximate solutions of the blind deblurring problem for these images using the MHDM with discrepancy principle for  $\tau = \sqrt{1.001}$ . Thereafter, we again run 1000 non-blind versions of the MHDM using 1000 “guessed” Gaussian kernels with variances between 1 and 12. In Table 1 we report the average ratio of the PSNR and SSIM values between the image obtained via blind MHDM and the best reconstructed

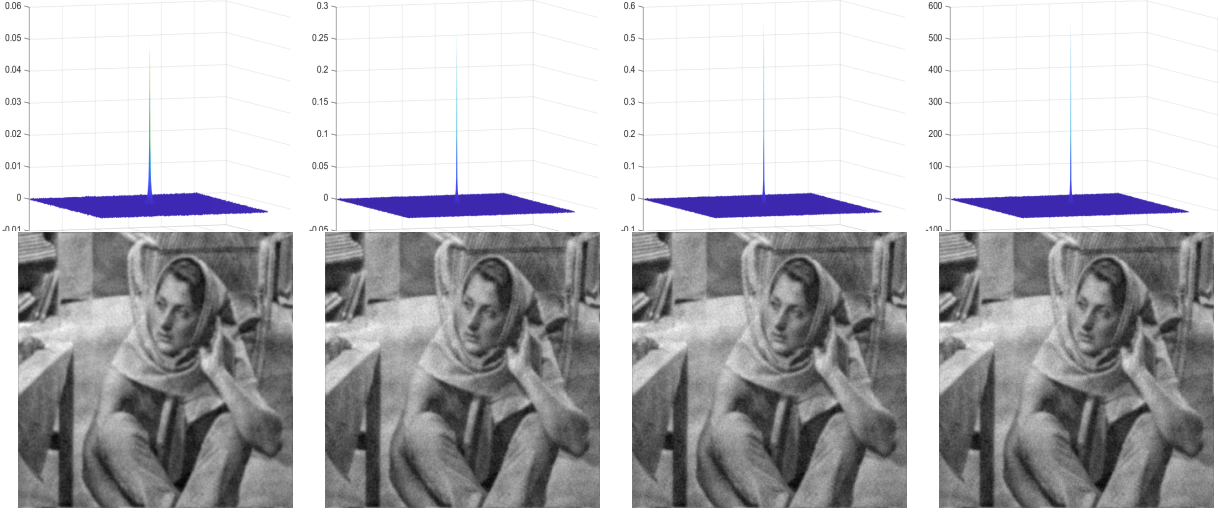

Figure 8: Kernel (top) and image (bottom) reconstructions obtained by running the blind-deconvolution MHDM with different initial parameters and rescaling the pixel values. From left to right:  $\lambda_0 = 2 \times 10^{-3}$  and  $\mu_0 = 6.3 \times 10^5$ ,  $\lambda_0 = 1.4 \times 10^{-4}$  and  $\mu_0 = 1 \times 10^3$ ,  $\lambda_0 = 2 \times 10^{-3}$  and  $\mu_0 = 1 \times 10^3$ ,  $\lambda_0 = 2 \times 10^3$  and  $\mu_0 = 1 \times 10^{-3}$ .

Table 1: Average ratio of PSNR and SSIM between the images obtained via blind and non-blind deconvolution MHDM sorted by noise level and blurring kernel respectively.

We note that, on average, the blind MHDM performs at most 13% worse than the optimal non-blind MHDM. These results indicate that the blind MHDM is a robust method that produces reasonable approximations. In particular, if the blurring kernel cannot be estimated with high accuracy, then the blind MHDM is superior to non-blind approaches.

#### 4.4 Experiment 2: Comparison blind MHDM vs variational blind deconvolution

We compare the blind deconvolution MHDM with a single-step variational regularization as in (18). To achieve a fair comparison of the methods, we optimize the regularization parameters. For the single-step regularization we proceed as follows: For a given ratio of regularization parameters  $\frac{\mu_0}{\lambda_0}$ , we compute regularized solutions of the blind-deconvolution problem by a grid search. As for the MHDM, we start this grid search by computing minimizers for an initial choice of parameters  $(\lambda, \mu)$ . The consecutive iterates  $(u_n^{var}, k_n^{var})$  are then obtained by computing solutions of (18) with parameters  $(\lambda_n, \mu_n) = (4^n \lambda_0, 4^n \mu_0)$ . This procedure is terminated once the discrepancy principle (10) with  $\tau = \sqrt{1.001}$  is satisfied. Therefore, the grid search and the MHDM are stopped according to the same rule which allows to investigate the effect of the multiscale decomposition. We then optimize both methods with respect to the ratio  $\frac{\mu_0}{\lambda_0}$  of the initial parameters. Here we consider optimal those parameters which maximize the PSNR value of the reconstructed image at the iterate satisfying the stopping rule. In order to observe the effects of the multiscale decomposition, we additionally require that both methods run for at least 10 iterations until the discrepancy principle is met. This way, we ensure that there are enough iterations such that the multiscale effects are observable on the reconstructions. For the experiments, we consider the same 144 test images as in the previous section. The average PSNR and SSIM values of the reconstructed images and the average relative  $L^2$ -error of the reconstructed kernels, as well as the corresponding standard deviations for both methods, are shown in Table 2 (averages and standard deviations for the different levels of noise) and Table 3 (averages and standard deviations for the different blurring kernels). We observe that, on average, the MHDM performs slightly better with respect to all considered metrics, apart from the average PSNR for noise with variance 0.0004. Based on a closer inspection of the experimental data, we notice that the advantage of the MHDM is, in part, due to the MHDM terminating more frequently with reconstructions

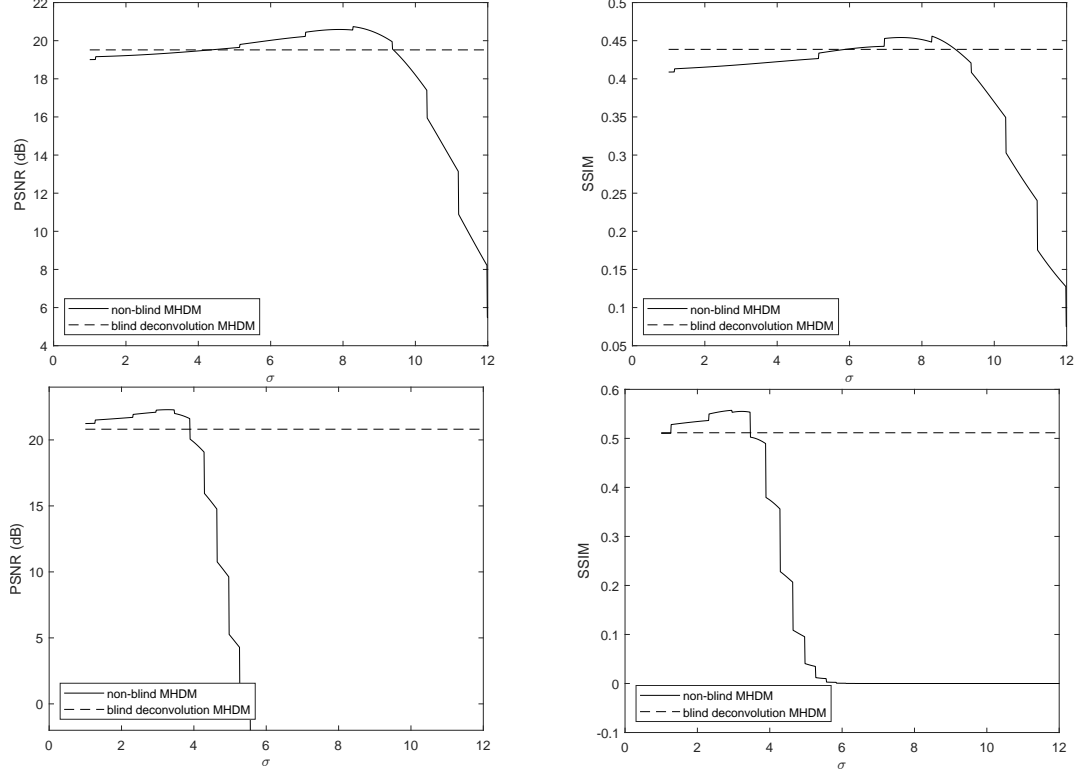

Figure 9: Top left: PSNR values for non-blind MHDH with guessed kernel for different guesses of the kernel and data  $f_1^\delta$ ,  
Top right: SSIM values for non-blind MHDH with guessed kernel for different guesses of the kernel and data  $f_1^\delta$ ,  
Bottom left: PSNR values for non-blind MHDH with guessed kernel for different guesses of the kernel and data  $f_2^\delta$ ,  
Bottom right: SSIM values for non-blind MHDH with guessed kernel for different guesses of the kernel and data  $f_2^\delta$ .

whose residual is closer to the stopping threshold  $\tau\delta^2$ . This is illustrated in Tables 4 and 5, where we omit those experiments in which the residuals of the MHDM and the variational grid search at the stopping index differ by more than  $0.1\tau\delta^2$ . We notice that, by neglecting these “outliers”, both methods perform even more similarly with respect to the quality indicators. By our numerical tests we thus conclude that the MHDM produces qualitatively similar approximations of the true image and kernel, and typically terminates with a residual closer to the stopping threshold. This means the MHDM is more robust than a grid search for single-step blind-deblurring.

Furthermore, we observe for both methods that the optimal ratio  $\frac{\mu_0}{\lambda_0}$  depends more on the true image and less on the kernel used to obtain the blurred image. Additionally, for a given image, there is only a slight difference between the optimal ratios of initial parameters for the MHDM and the grid search in the single-step approach.

## 5 Conclusion

We introduce the Multiscale Hierarchical Decomposition Method for the blind deconvolution problem and show convergence of the residual in the noise-free case and then in the noisy data case by employing a discrepancy principle. To demonstrate the efficiency and behavior of the proposed method, we focus on employing fractional Sobolev norms as regularizers and develop a way to compute the appearing minimizers explicitly in a pointwise manner. We want to stress that in our experience, any variational approach to blind

deconvolution should incorporate prior information on the expected blurring kernel. In our setting, this was done by enforcing a positivity constraint on the Fourier transform of the kernels, thus favoring, e.g., Gaussian structures. Numerical comparisons with a single-step variational method and a non-blind MHDM show that our approach produces comparable results, in a more stable manner. Additionally, the scale decomposition of both reconstructed kernel and image provides a meaningful interpretation of the involved iteration steps. For future work, this opens up the possibility to modify the method based on prior information of the underlying true solution. By using multiple penalty terms throughout the iteration, one could construct approximate solutions that admit different structures at different levels of detail. Nonetheless, we believe that at first a better understanding of iterates' convergence behavior is necessary to systematically refine the method. In future research, we aim to adapt the proposed method for parameter identification problems with unknown forward operator and the classification of blurring operators occurring in real applications.

## 6 Acknowledgements

We thank Michael Quellmalz (Technische Universität Berlin) for his valuable remarks and literature suggestion on the positivity of Fourier transforms. We want to thank the referee for the useful and constructive comments that greatly helped to improve the manuscript. This research was funded in part by the Austrian Science Fund (FWF) [10.55776/DOC78]. For open access purposes, the authors have applied a CC BY public copyright license to any author-accepted manuscript version arising from this submission.
